HANDBOOK OF CHEMISTRY

A reference volume for all requiring ready access to chemical and physical data used in laboratory work and manufacturing

Compiled and Edited by

NORBERT ADOLPH LANGE, PH. D.

Registered Professional Engineer; Member of the American Chemical Society; Fellow of the American Institute of Chemists

Assisted by

GORDON M. FORKER, B. S. (CHEM. ENG.)

General Electric Company, Cleveland, Ohio

TENTH EDITION

McGraw-Hill Book Company, Inc.

New York Toronto London

PREFACE

This book is the result of a number of years' experience in the compiling and editing of data useful to chemists. In it an effort has been made to select material to meet the needs of chemists who cannot command the unlimited time available to the research specialist, or who lack the facilities of a large technical library which so often is not conveniently located at many manufacturing centers. If the information contained herein serves this purpose, the compiler will feel that he has accomplished a worthy task. Even the worker with the facilities of a comprehensive library may find this volume of value as a time-saver because of the many tables of numerical data which have been especially computed for this purpose.

Every effort has been made to select the most reliable information and to record it with accuracy. Many years of occupation with this type of work bring a realization of the opportunities for the occurrence of errors, and while every endeavor has been made to prevent them, yet it would be remarkable if the attempts towards this end had always been successful. In this connection it is desired to express appreciation to those who in the past have called attention to errors and it will be appreciated if this be done again with the present compilation for the publishers have given their assurance that no expense will be spared in making the necessary changes in subsequent printings.

It has been aimed to produce a compilation complete within the limits set by the economy of available space. One difficulty always at hand to the compiler of such a book is that he must decide what data are to be excluded in order to keep the volume from becoming unwieldy because of its size. He can hardly be expected to have an expert's knowledge of all branches of the science nor the intuition necessary to decide in all cases which particular value to record especially when many differing values are given in the literature for the same constant. If the expert in a particular field will judge the usefulness of this book by the data which it supplies to him from fields other than his specialty and not by the lack of highly specialized information in which only he and his coworkers are interested (and with which he is familiar and for which he

would never have occasion to consult this compilation), then an estimate of its value to him will be apparent. However, if such specialists will call attention to missing data with which they are familiar and which they believe others less specialized will also need, then works of this type can be improved in succeeding editions.

Many of the gaps in this volume are caused by the lack of such information in the literature. It is hoped that to one of the most important classes of workers in chemistry, namely the teachers, the book will be of value not only as an aid in answering the most varied questions with which they are confronted by interested students, but also as an inspiration through what it suggests by the gaps and inconsistencies, challenging as they do the incentive to engage in the creative and experimental work necessary to supply the missing information.

While the principal value of the book is for the professional chemist or student of chemistry, it should also be of value to many people not especially educated as chemists. Workers in the natural sciences—physicists, mineralogists, biologists, pharmacists, engineers, patent attorneys, and librarians, are often called upon to solve problems dealing with the properties of chemical products or materials of construction. For such needs this compilation supplies helpful information and will serve not only as an economical substitute for the costly accumulation of a large library of monographs on specialized subjects, but also as a means of conserving the time required to search for information so widely scattered throughout the literature. For this reason especial care has been taken in compiling a comprehensive index and in furnishing cross references with many of the tables.

It is hoped that this book will be of the same usefulness to the worker in science as is the dictionary to the worker in literature, and that its resting place will be on the desk rather than on the book shelf.

N. A. Lange.

Cleveland, Ohio.
May 2, 1923.

ACKNOWLEDGMENT

Grateful acknowledgment is hereby made of an indebtedness to my former teachers and many members of the chemical profession who by their criticisms and suggestions in past years have been of unconscious assistance towards the preparation of this book. Sincerest appreciation is likewise expressed to the various manufacturers, trade associations, and the managements of technical publications who have supplied and permitted reprinting of certain information as acknowledged within the text. In particular is acknowledgment made of the services of the following who have been of material assistance in this work:—

E. A. ARNOLD, PH.D.,
Case Institute of Technology,
Cleveland, Ohio.

W. L. BADGER,* M.S.,
Ann Arbor, Michigan.

ROGER G. BATES, PH.D.,
National Bureau of Standards,
Washington, D. C.

FIRST AID MEASURES FOR ACCIDENTS AND ANTIDOTES OF POISONS

By W. F. von Oettingen, M. D., Ph. D.

The following directions are intended as first aid measures for accidents and different forms of poisoning. In laboratories connected with institutions or plants which have first aid stations or emergency hospitals, any injury should be reported immediately. If such facilities are not available, and whenever the case is of a more serious nature, a physician should be summoned at once and, in order to avoid any delay, the items in parentheses should be ready for his use upon his arrival.

Treatment of Burns

In any case of extensive burns of any degree, call physician.

1. From fire, steam and hot objects.

(*a*) *First degree* (*reddening*): Oil dressing or bland ointment; gauze saturated with pure vegetable or mineral oil.

(*b*) *Second degree* (*blisters*): Cover blister with sterile gauze saturated with olive oil or some burn ointment; apply oil dressing until the wound is healed.

(*c*) *Third degree* (*destruction of tissue*): Cover wound with a sterile dressing and call a physician. (Prepare sterile bandaging material; arrange facilities for sterilizing instruments with boiling water; in case of shock: caffeine sodio-benzoate or salicylate for hypodermic injection; normal saline solution.)

2. From acids (hydrochloric, nitric, phosphoric, and sulfuric acids, and chlorine or bromine). Wash with large quantities of water, then with 5% sodium bicarbonate solution, and apply oil dressing. (In case of extensive and severe burns prepare materials for physician as directed under 1, *c*.)

Burns from **hydrofluoric acid.** Wash burn immediately in cold running water until the white coagulated appearance of the area has been replaced by redness, or for a period of at least 4 to 6 hours. Then apply a freshly prepared 20% suspension of magnesium oxide in glycerol. (Prepare a 10% magnesium sulfate solution; material for oil dressing; facilities for the sterilization of instruments with boiling water.)

3. From alkalies: Wash the injury with large quantities of water, and cover the wound with an oil dressing or bland ointment. (In case of extensive burns prepare materials for physician as directed under 1. *c*.)

4. From phenols: Wash liberally with alcohol and then apply an oil dressing. (In case of extensive burns prepare materials for physician as directed under 1, *c.*)

5. Burns of the eye should be flushed first with large quantities of water, and then in case of alkalies with 2% boric acid solution, and in case of acids with 3% sodium bicarbonate solution, after which the eye should be covered with gauze moistened with olive oil.

Treatment of Cuts

Clean the wound mechanically using *sterile* forceps or *sterile* gauze and paint the area *surrounding* the injury with 3.5% tincture of iodine.

If the cut is *small*, scrub with soap and water, cover with sterile gauze and bandage or adhesive tape.

If the cut is *severe* and bleeding freely apply a ligature between the site of the injury and the heart in case the blood is red and the flow intermittent; if the blood is dark and the flow continuous, apply the ligature between the injury and the periphery. Cover the wound with sterile gauze until arrival of the physician. (Prepare sterile bandaging material, facilities for sterilizing instruments with boiling water; and in case of severe hemorrhage several liters of sterilized physiological saline solution (0.9% solution of sodium chloride in water) and caffeine sodio-benzoate for hypodermic injection.)

Collapse

Lay the patient flat on the floor and let him inhale *dilute* vapors of ammonia or smelling salts; stimulate the skin by rubbing with stiff brushes. Administer whiskey or coffee *if patient is able to swallow.* In case the respiration is shallow or arrested, start artificial respiration preferably with simultaneous administration of oxygen or oxygen-6% carbon dioxide mixture. (Prepare camphor oil, caffeine sodio-benzoate for hypodermic injection, sterilized physiological saline solution (0.9% solution of sodium chloride in water) and a cylinder of oxygen-6% carbon dioxide.)

Treatment of Poisonings

Call physician. If cause is known, follow immediately the directions given below.

Acids. When taken orally, rinse the mouth with water then with 5% sodium bicarbonate; give milk and a suspension of 10 grams of magnesium oxide (magnesia) in 150 cc of water; or limewater and oil; or a thin flour paste. (Prepare sterilized physiological saline

solution as directed under *collapse*, camphor oil and solution of caffeine sodio-benzoate.

Alcohols. Give large quantities of warm water and if possible gastric lavage, emetics such as mustard water, and coffee. (Prepare caffeine sodio-benzoate, and oxygen-6% carbon dioxide mixture; stomach tube.)

Aldehydes. Give a tumbler full of 0.2% ammonia solution followed within a few minutes by milk. (Prepare stomach tube, caffeine sodio-benzoate, physiological saline solution as directed above, and oxygen.)

Alkaloids. Immediately give one or two tablespoonfuls of purified charcoal in suspension in a glass of water; then give an emetic such as soap water. (Prepare caffeine sodio-benzoate, chloral hydrate, chloroform, and oxygen-6% carbon dioxide mixture.)

Ammonia. Administer large quantities of water containing vinegar or lemon juice and later give olive oil. (Prepare materials as given above for *acids* for use of the physician upon his arrival.) If inhaled, transfer patient to fresh air and keep him at rest.

Aniline. If taken by mouth, give large quantities of soap water, administer oxygen freely, combined with artificial respiration if necessary, saline cathartics, *give no alcohol or oils.* If inhaled, transfer patient to fresh air, let him have absolute rest and let him inhale oxygen. (Prepare materials as given under *acids.* Keep oxygen or oxygen-6% carbon dioxide mixture ready.)

Arsenic or Antimony. Give an emetic such as soap water and a cathartic such as epsom salts; *do not rely upon chemical antidotes.* (Prepare stomach tube, physiological saline, and caffeine sodio-benzoate.)

Arsine. Absolute rest; free administration of oxygen. (Prepare facilities for sterilizing instruments with boiling water, caffeine sodio-benzoate, and oxygen.)

Barium salts. Give emetics such as soap water, and saline cathartics such as epsom or Glaubers salts. (Prepare stomach tube, and a 25% magnesium sulfate solution for hypodermic injection.)

Benzene. If taken by mouth, give emetics such as soap water or mustard water, cathartics, artificial respiration with simultaneous administration of oxygen, coffee. (Prepare stomach tube, caffeine sodio-benzoate, and oxygen.) If inhaled, transfer patient to fresh

air, prevent chilling, let him have absolute rest, if necessary let him inhale oxygen until physician arrives.

Carbolic acid. Give soap water as an emetic, large quantities of water, syrup of lime, or a solution of one part of potassium permanganate in 4000 parts of water. (Prepare stomach tube, caffeine sodio-benzoate, oxygen.)

Carbon monoxide, Ethylene, Acetylene, Illuminating gas. Transfer patient to fresh air, prevent chilling, administer oxygen, if respiration is slow, irregular or intermittent, this should be combined with the administration of oxygen and artificial respiration in case the respiration has stopped. (Prepare caffeine sodio-benzoate, oxygen.)

Chlorine, Bromine. If taken orally, rinse mouth with 3% sodium bicarbonate and magnesium oxide in water; give milk and suspension of 10 g. magnesium oxide in 150 cc of water. (Make preparations for the arrival of physician as directed under *acids*.) If inhaled, follow the treatment as given under *phosgene*.

Hydrocyanic acid, Cyanides. If taken orally, give a 1% solution of sodium thiosulfate or 0.025% solution of potassium permanganate alkalinized with sodium bicarbonate. Give an emetic such as mustard water or soap water and have patient inhale the contents of one pearl of amyl nitrite. Give artificial respiration with free administration of oxygen. (Prepare caffeine sodio-benzoate, oxygen-6% carbon dioxide mixture, stomach tube, several liters of an aqueous 0.05% potassium permanganate solution.) If inhaled, start with inhalation of one pearl of amyl nitrite and artificial respiration with administration of oxygen.

Hydrogen sulfide. Artificial respiration with simultaneous administration of oxygen. (Prepare oxygen-6% carbon dioxide mixture.)

Iodine. Give an emetic such as soap water; a 1% aqueous solution of sodium thiosulfate (Hypo); starch paste; milk. (Prepare stomach tube and several liters of an aqueous 1% sodium thiosulfate solution.)

Lead compounds. Give large quantities of epsom salt. (Prepare stomach tube.)

Mercury compounds. Immediately give three raw eggs in a quart of milk and an emetic such as soap water. (Prepare stomach tube, hydrogen peroxide, and an hypophosphite-peroxide mixture composed of 1 gram sodium hypophosphite, 5 cc hydrogen peroxide, and 10 cc of water for each 0.1 gram of mercuric chloride in the stomach of the patient.)

Morphine alkaloids. Give strong coffee, hot bath and artificial respiration. (Prepare oxygen-6% carbon dioxide mixture, caffeine sodio-benzoate, 0.1% atropine sulfate solution for hypodermic use, stomach tube, and several liters of a 0.1% solution of potassium permanganate in water.)

Nitric vapors. *Absolute rest ! ! !*, even in moderate poisoning; inhalation of oxygen. (Prepare caffeine sodio-benzoate, facilities for sterilization of instruments with boiling water, and physiological saline solution as directed under *collapse.*)

Nitro compounds. Give emetic such as mustard water, and saline cathartics; *avoid alcohol, fats* and *oil.* (Prepare stomach tube, caffeine sodio-benzoate, and oxygen-6% carbon dioxide mixture.)

Oxalic acid. Give emetic such as mustard water; syrup of lime, lime water; castor oil. (Prepare stomach tube; sterile aqueous 3% solution of calcium lactate or calcium gluconate in ampoules for intravenous injection.)

Permanganate. Give water; emetic such as mustard water; starch paste. (Prepare stomach tube.)

Phosgene. *Absolute rest ! ! !*, even in moderate cases; inhalation of oxygen. (Prepare caffeine sodio-benzoate, and facilities for sterilization of instruments with boiling water.)

Phosphorus. Give 200 cc of a 0.2% aqueous solution of copper sulfate. *Avoid fats and oils.* (Prepare stomach tube, several liters of a 0.2% aqueous solution of copper sulfate, a 0.1% aqueous solution of potassium permanganate, liquid petrolatum.)

Pyridine. Give large quantities of tea or coffee; artificial respiration. (Prepare stomach tube, caffeine sodio-benzoate, and oxygen.)

Sodium fluoride, Roach powder insecticide. Give lime water or weak solutions (2%) of calcium chloride. (Prepare for gastric lavage, keep lime water ready and sterile 1% solution of calcium chloride for intravenous injection, or calcium gluconate for intramuscular injection.)

Silver compounds. Give large quantities of common salt or sodium chloride solution. (Prepare stomach tube.)

Tin compounds. Give emetic such as soap water; milk of magnesia; oils. (Prepare stomach tube, caffeine sodio-benzoate.)

Zinc compounds. Give emetic such as soap water, and an egg in milk. (Prepare stomach tube, caffeine sodio-benzoate.)

A TABLE OF COMMON

Prepared by Committees of the National Fire Protection

Tentatively adopted 1928, *adopted* 1929,

These columns are informative only; it is not considered necessary that the material be kept or stored only in the containers as listed, nor that each package be labeled.

Usual Shipping Container	Life Hazard	Fire Fighting Phases
Acetic Acid (Glacial) Glass carboys and barrels. Expands on solidification and may burst container unless kept at a temperature above 16° C. (60.8° F.).	May cause painful burns of skin.	Extinguishing agent, water.
Acetone Carboys, steel drums, tank cars.	Toxicity of a comparatively low order.	Lighter than water. (Sp. gr. 0.792) but soluble in it in all proportions. Water, particularly in the form of spray, is the best extinguisher. Carbon dioxide may also be used. Automatic sprinkler systems or total-flooding carbon dioxide systems may be employed for protection in storage rooms.
Aluminum Dust Barrels or boxes.		Smother with sand, ashes, or rock dust. Do not use water, which may cause explosion.
Aluminum Resinate Wooden barrels.		
Ammonia (Anhydrous) Steel cylinders or steel tank cars.	Irritant. An outstanding serious effect produced by ammonia in concentrations of the order of ½% by volume for duration of exposure of the order of ½ hour is blindness. A concentration of 0.03% of ammonia in air, for duration of exposure of the order of ½ to 1 hour, according to Lehmann, does not cause serious effects.	Soluble in water. Hose streams comparatively effective in removing the gas from the atmosphere.

HAZARDOUS CHEMICALS

Association and American Chemical Society.

amended 1931, 1935, 1938, 1939, 1941, 1942.

The requirements in the table on the storage of containers refer to chemicals in usual containers, and are not intended to apply to small bottles of chemicals such as are found in drug stores and chemical laboratories.

Fire Hazard	Storage
Dangerous in contact with chromic acid, sodium peroxide or nitric acid; yields moderately flammable vapors above flash point 104° F.	Safeguard against mechanical injury. Isolate from oxidizing materials as noted under Fire Hazard.
A volatile liquid. Gives off vapors which form with air flammable and explosive mixtures. Flash point −16° C. (3° F.). Explosive range 2.55% to 12.8% (upward propagation). The ignition temperature is comparatively high, being within the range 538° to 566° C. (1000° to 1050° F.). The vapors are heavier than air (vapor density 2). Fire hazard slightly less than that of gasoline.	Safeguard containers against mechanical injury. Only electrical equipment of the explosion-proof type, Group D classification, permitted in atmospheres containing acetone vapor in flammable proportions.
Forms flammable and explosive mixtures with air.	Keep in dry place. In case of fire do not use water; it may cause an explosion.
Combustible.	Storage should be ventilated and safeguarded as for oil storage building.
Gas density 0.60 (air = 1). Not flammable in air except in comparatively high concentration, which is seldom encountered under practical conditions, the low limit of the flammable or explosive range being about 15% to 16% and the upper limit about 25% to 26% by volume (horizontal propagation). The presence of oil will increase the fire hazard. Ammonia aqua does not burn.	Safeguard against mechanical injury and excessive heating of cylinders or tanks. Fire-resistive storage recommended. In combustible buildings or if near combustibles, sprinklered storage recommended. Isolate from other chemicals, particularly chlorine, bromine, iodine and mineral acids.

Usual Shipping Container	Life Hazard	Fire Fighting Phases
Ammonium Perchlorate		
Wooden barrels or kegs and glass bottles.		
Antimony Pentasulfide; (Golden Antimony Sulfide) Sb_2S_5		
Fiber drums or tins. Used in manufacture of matches, ammunition and fire works, and of certain rubber compounds.	Gaseous products of combustion contain sulfur dioxide and are irritating and corrosive.	Practically insoluble in water. Use water.
Barium Chlorate		
Wooden boxes, barrels or kegs.		See potassium chlorate.
Barium Nitrate		
Wooden boxes; barrels.	Soluble in water. Poisonous when taken internally.	See sodium nitrate.
Barium Peroxide		
Tightly closed metal containers packed in wooden boxes or barrels; or in bulk in metal barrels or drums.		Smother with sand, ashes, or rock dust. Do not use water.
Benzoyl Peroxide (Dry granular or powdered wet)		
Dry granular material in individual one-pound containers inside wooden boxes; finely powdered material shipped wet (30% water by weight) in glass containers placed inside tightly sealed metal containers in wooden boxes or in aluminum drums.	Dust irritating to eyes and lungs. Use goggles and dust respirator in dusty atmospheres.	Water, carbon dioxide, foam, sand, soda ash, or rock dust may be used as extinguishing agents.
Bleaching Powder; Calcium Hypochlorite; Chlorinated Lime; Chloride of Lime (incorrect name)		
Air-tight tin containers, wooden barrels, and steel drums. Encountered in paper, textile, disinfectant and alkali industries; also where water purification processes are employed.	Corrosive. Irritating to skin, eyes, and lungs. See chlorine.	Fires where the compound is present may be fought with water, preferably spray. Protect eyes and skin, using gas mask of a type approved by Bureau of Mines.

HAZARDOUS CHEMICALS

	Fire Hazard	Storage
	Oxidizing material. May explode in a fire. Hazard classes with potassium chlorate.	Safeguard against mechanical injury. Isolate from mineral acids, also from combustibles.
	Combustible. Readily ignited by a small flame. Hazardous in contact with oxidizing material. Yields flammable hydrogen sulfide on contact with mineral acid.	Safeguard against mechanical injury. Isolate from acids, chlorates, nitrates, and other oxidizing agents.
	Oxidizing material. Hazard classes with potassium chlorate.	Isolate.
	Oxidizing material. Hazard in class with sodium nitrate.	Do not store with combustible materials.
	Oxidizing material. Hazard in class with sodium peroxide.	Do not store with combustible materials.
	Highly flammable in the dry state. Strong supporter of combustion. Do not subject dry material to heat of friction or grinding. Not miscible with water.	Store in a cool ventilated place. Powder should be stored with not less than 30% water by weight. Keep away from all sources of heat and separate from all combustible materials and acids.
	Not combustible but evolves chlorine and at higher temperatures oxygen. With acids or moisture evolves chlorine freely at ordinary temperatures. See chlorine.	Store in cool, dry, well ventilated place away from combustibles. See chlorine. Rupture of drums containing bleaching powder, particularly if the chlorine content is high, may result from exposure to heat.

A TABLE OF COMMON

Usual Shipping Container	Life Hazard	Fire Fighting Phases
Borneol Barrels, kegs, boxes and tins.		See camphor.
Bromine Glass bottles; earthen jugs. Bottles should be surrounded by incombustible packing.	Corrosive; at ordinary temperatures gives off poisonous suffocating vapors.	
Bronze Dust Barrels or boxes.		Smother with sand or ashes.
Butane Steel cylinders.		
Calcium Carbide Iron drums and tin cans.	Serious under fire conditions.	Smother with sand or ashes. Do not use water.
Calcium Oxide; Quick Lime Wooden barrels and bags.		
Camphene Tins.		Smother with sand or ashes. Avoid water.
Camphor Tins and wooden kegs.		Smother with sand or ashes. Chemical streams. Avoid water.
Carbolic Acid—*See Phenol.*		
Carbon Disulfide Small glass, earthenware, or metal containers packed in outside barrels or boxes (See I. C. C. Regulations). Steel drums, steel tank cars. Carbon disulfide should never be transferred by means of air. Use inert gas, water, or pump. Use a wood measuring stick for	Toxic. 3200 to 3850 parts of vapor per million (0.32 to 0.385% by volume) may cause dangerous illness in ½ to 1 hour. Direct contact with the skin should be avoided. Products of combustion contain sulfur dioxide, which in concentrations of 0.2% by volume in air may cause serious injury in	Heavier than water (Sp. gr. 1.29) and sparingly soluble in it. Use sand, carbon dioxide, or other inert gas as extinguishing agents. Cooling and blanketing action of water may be utilized in case of fires in metal containers or tanks. Total-flooding carbon dioxide systems may be employed for protection in storage rooms. Foam not effective. Do not

HAZARDOUS CHEMICALS

Fire Hazard	Storage
Combustible. Hazard similar to camphor.	Store in well-ventilated compartment or building.
Causes oxidizing effect, resulting in heating and may cause fire when in contact with organic material.	Isolate; safeguard against mechanical injury.
When aluminum is present forms flammable and explosive mixtures with air. Composition usually free from aluminum.	Bronze dust free from aluminum not considered dangerous.
Flammable gas under pressure. Classes with gasoline vapor in fire hazard.	Safeguard against mechanical injury. Keep cool.
Gives off acetylene gas on contact with water or moisture.	Store in dry, well-ventilated place in accordance with N.F.P.A. Standards.
Heats upon contact with water or moisture and may cause ignition of organic material. Swells when moist and may burst container.	Isolate; store in dry place away from water or moisture.
When heated gives off flammable vapors. Classes with turpentine.	Isolate; keep in unheated compartment away from fire or heat.
Flammable; gives off flammable vapors when heated which may form explosive mixture with air. Flash point 180° F.	Detach from other storage. Keep in well-ventilated room remote from fire.
A highly volatile liquid with an offensive odor, giving off even at comparatively low temperatures vapors which form with air flammable and explosive mixtures. Flash point −30° C. (−22° F.). Flammable range 1% to 50% (upward propagation). The ignition temperature is dangerously low, being about 100° to 106° C. (212° to 223° F.). It is endothermic, and the vapor may be ignited by a heavy blow. The vapors are heavier than air (vapor density 2.62), and may travel a considerable distance to a source of ignition and flash back. More hazardous than gasoline.	Isolate and safe-guard containers against mechanical injury and metallic blows, and keep in unheated compartment away from sunlight and any source of ignition, including electric lighting fixtures and other electrical equipment. Storage tanks should be constructed over concrete basins containing water, and the carbon disulfide kept blanketed

Usual Shipping Container	Life Hazard	Fire Fighting Phases
Carbon Disulfide (*Continued*)		
measuring contents of storage tanks or tank cars. Tank cars when being loaded or unloaded should be well grounded. Do not dispose of carbon disulfide by pouring it on the ground. Provide a safe place for burning it.	½ hour or less. Often poisonous carbon monoxide is present in the products of combustion.	use carbon tetrachloride. Use of gas masks or oxygen helmets of the type approved for the purpose by U. S. Bureau of Mines recommended.
Charcoal (Wood)		
Boxes, barrels, bags, or bulk.	There is danger from carbon monoxide poisoning during burning unless adequate ventilation is provided.	Use water, completely extinguishing the fire, after which the storage pile should be moved.
Chinese Wax		
Burlap bags and wooden barrels.		
Chlorine		
Steel cylinders and tank cars.	Corrosive. Irritating to eyes and mucous membrane. Toxic. 0.004% to 0.006% by volume in air causes dangerous illness in ½ to 1 hour.	Use gas masks on entering atmospheres containing chlorine gas. If, however, concentration is high, or there is doubt as to the degree of concentration, use oxygen helmet of a type approved for such use by U. S. Bureau of Mines.
Chromium Trioxide or Chromium Anhydride CrO_3 (often called "Chromic Acid")		
Iron drums and glass bottles. It is used in chromium plating, in electric batteries, and in photography.	Irritating to skin. Poisonous.	Use water, completely extinguishing the fire, after which the storage pile should be removed.
Cobaltous Nitrate		
Wooden barrels.		
Colophony; Rosin		
Barrels.		
Copper Nitrate		
Wooden barrels and	Poisonous when taken internally. Soluble in water.	

Fire Hazard	Storage
	with water or inert gas at all times.
Spontaneously ignitable when freshly calcined and exposed to air, or when wet; hazardous when freshly ground and tightly packed.	Isolate; prevent dust accumulations; ventilate well; make daily inspections.
Combustible.	Detach from other storage.
Is not combustible in air but reacts chemically with many common substances and may cause fire or explosion when in contact with them. See remarks under "Storage." Dangerous to neutralize chlorine in a room with ammonia.	Isolate from turpentine, ether, ammonia gas, illuminating gas, hydrocarbons, hydrogen, and finely divided metals. Safeguard against mechanical injury of containers.
Oxidizing material; will ignite on contact with acetic acid and alcohol. Chars organic material such as wood, sawdust, paper, or cotton, and may cause ignition. Combustible material in presence of chromium trioxide when ignited burns with great intensity. May cause explosion in fire.	Isolate.
Oxidizing material. Classes with sodium nitrate.	See sodium nitrate.
Combustible; gives off flammable vapors when heated.	Ventilate storage; avoid dust; keep away from fire or heat.
Oxidizing material. Hazard classes with sodium nitrate.	Safeguard against mechanical injury; isolate. See sodium nitrate.

	Usual Shipping Container	Life Hazard	Fire Fighting Phases
Cyclopropane	Steel cylinders.	Anaesthetic.	Use water to cool cylinders not on fire. If gas is burning at valves or safety releases, usually the best course to follow is not to disturb or attempt to extinguish flame. To do so will cause the release of unburned gas and quickly create highly dangerous explosive atmospheres. If cylinder is mounted on an anaesthetic machine or truck, it may be possible to move it to a safe place. Carbon dioxide or carbon tetrachloride are best extinguishing agents.
Didymium Nitrate	Wooden kegs.		
Dioxane	Glass bottles, metal cans, and metal drums.	Irritant and toxic in high concentrations.	Water best extinguishing agent. Slightly heavier than and completely soluble in water (Sp. gr. 1.03).
Ethyl Ether	Glass bottles or tin cans in boxes, steel drums.	Anaesthetic. See National Board of Fire Underwriters' Recommended Safeguards for the Installation and Operation of Anaesthetical Apparatus Employing Combustible Anaesthetics.	Lighter than water. (Sp. gr. 0.7135.) Soluble in about ten times its own volume of water. Water may be utilized only to cool metal containers. Best extinguishing agents are carbon dioxide and sand, also carbon tetrachloride in case of fires involving limited amounts of ether. Total-flooding carbon dioxide systems may be employed for protection in storage rooms.
Ethylene	Steel cylinders.	Anaesthetic.	Use water to cool cylinders not on fire. If gas is burning at valves or safety releases, usually the best course to follow is not to disturb or attempt to extinguish flame. To do so

	Fire Hazard	Storage
	Highly flammable gas. Forms flammable and explosive mixtures with air or oxygen. Explosive range 2.40% to 10.4% (upward propagation). Only electrical equipment of the explosion-proof type, Group C classification tentative pending further tests, permitted in atmospheres containing cyclopropane in flammable proportions.	Isolate from oxygen cylinders and store in a cool, well ventilated storeroom.
	Oxidizing material. Classes with sodium nitrate.	Isolate. See sodium nitrate.
	Moderately volatile flammable liquid. Flash point 54° F. Explosive range 1.97% to 22.25% (upward propagation). Vapors are heavier than air (vapor density 3.03). Capable of forming peroxides under certain conditions, and there may be danger of explosion if redistilled, unless certain precautions are taken.	Isolate and safeguard against mechanical injury.
	A highly volatile liquid, giving off even at comparatively low temperatures vapors which form with air or oxygen flammable and explosive mixtures. Explosive range 1.85% to 36.5% (upward propagation). The ignition temperature is comparatively low, being approximately 180° C. (356° F.). Spontaneously explosive peroxides sometimes form on long standing or exposure in bottles to sunlight. The vapors are heavier than air (vapor density 2.6) and may travel a considerable distance to a source of ignition and flash back. More hazardous than gasoline.	Safeguard containers against mechanical injury. Isolate and keep in unheated compartment away from sunlight and any source of ignition. Only electrical equipment of the explosion-proof type, Group C classification, permitted in atmospheres containing ether vapor in flammable proportions.
	Highly flammable gas. Forms flammable and explosive mixtures with air or oxygen. Explosive range 2.75% to 28.6% (upward propagation). Ignition temperature about 450° C. (842° F.). Slightly lighter than air (density 0.97). The gas is spontaneously explosive in sunlight with chlorine.	Isolate from oxygen cylinders and store in a cool, well ventilated storeroom.

Usual Shipping Container	Life Hazard	Fire Fighting Phases
Ethylene (*Continued*)		will cause the release of unburned gas and quickly create highly dangerous explosive atmospheres. If cylinder is mounted on an anaesthetic machine or truck, it may be possible to move it to a safe place. In a closed storeroom carbon dioxide or carbon tetrachloride are best extinguishing agents.
Ferric Nitrate		
Wooden barrels.		
Formic Acid		
Barrels and carboys.	Corrosive; has caustic effect on the skin.	
Fulminate of Mercury		
Fulminate of Silver		
Hydrochloric Acid (Muriatic Acid)		
Tank cars (rubber-lined), carboys, and glass bottles.	Aqueous solution is corrosive, irritating, and poisonous. Fumes are corrosive and irritating to mucous membranes.	Use water or chemically basic substances such as soda ash or slaked lime.
Hydrocyanic Acid (Prussic Acid)		
Cylinders, or when completely absorbed in inert material in metal cans with outside wooden boxes.	Poisonous. Few breaths may cause unconsciousness and death. Avoid contact with the skin.	The gas is slightly lighter than air. Soluble in water. Water is the best extinguisher. When entering premises where used or stored during a fire, use oxygen helmet or gas mask equipped with canister of a type approved by the Bureau of Mines for hydrocyanic acid.
Hydrofluoric Acid (HF)		
Aqueous solution in lead carboys and wax or gutta percha bottles.	Acid and its vapors highly toxic and irritating to skin, eyes and respiratory tract. Fumes produced by contact with ammonia and many metals poisonous. May be neutralized with	Use water in case of fires involving hydrofluoric acid. Use oxygen helmet of a type approved for such use by the U. S. Bureau of Mines on entering atmospheres known to contain hydrofluoric acid vapors.

	Fire Hazard	Storage
	Only electrical equipment of the explosion-proof type, Group C classification, permitted in atmospheres containing ethylene in flammable proportions.	
	Oxidizing material.	Isolate. Safeguard against mechanical injury.
	Flammable; gives off flammable vapors which may form explosive mixtures with air.	Safeguard against mechanical injury.
	High explosive.	Explosive restrictions.
	High explosive.	Explosive restrictions.
	Not combustible (in air) but if allowed to come in contact with common metals hydrogen is evolved, which may form explosive mixtures with air.	Safeguard containers against mechanical injury. Keep away from oxidizing agents, particularly nitric acid and chlorates. Avoid contact by leakage or otherwise with all common metals.
	Forms flammable and explosive mixtures with air. Explosive range 6% to about 40% by volume (horizontal propagation). Concentrations of the gas ordinarily employed for fumigation (1% or less) are considerably below the lower limit of flammability (6% by volume). Some methods of fumigation, however, are employed which temporarily yield flammable mixtures even though the final concentration is low.	Isolate. Keep away from any source of heat. Safeguard containers against mechanical injury.
	Colorless, volatile liquid. Not combustible but reacts with glass and most substances, platinum being an exception. Aqueous solution also attacks glass and several metals.	Isolate. Ventilate. Safeguard against mechanical injury. Encountered in glass works and chemical laboratories. Used to remove sand from castings and in the manufacture of filter paper. Vapors have been known to cause ser-

Usual Shipping Container	Life Hazard	Fire Fighting Phases
Hydrofluoric Acid (HF) (*Continued*)		
	chalk. Bicarbonate of soda solution may be immediately applied to burns as first-aid and used as gargle.	
Hydrofluosilicic Acid		
Lead carboys, hard rubber or paraffin bottles.	Corrosive.	
Hydrogen Peroxide (27.5 per cent by weight)		
Glass carboys, aluminum drums, aluminum tank cars (all containers must be vented).	Prolonged exposure to vapor irritating to eyes and lungs. Causes skin irritation. Use goggles to protect eyes from splash.	Use water.
Hydrogen Sulfide (Sulfuretted Hydrogen)		
Steel cylinders.	Toxic. 0.05 to 0.07 per cent by volume in air causes dangerous illness in ½ to 1 hr. Should be used under hoods in chemical laboratories to avoid danger of breathing dangerous concentrations.	Use gas masks in entering atmospheres containing hydrogen sulfide. If, however, concentration is high, use oxygen helmet of a type approved for such use by U. S. Bureau of Mines.
Lead Nitrate		
Wooden barrels.	Poisonous.	
Lime (unslaked)— *See Calcium Oxide.*		
Magnesium		
Shavings or powder in tightly closed metal or metal-lined containers. Ingots and bars in ordinary boxes.	Serious under fire conditions. Danger of explosion and from flying particles. Do not attempt to smother unless at a safe distance, or else protection is provided for eyes and face.	Smother with an excess of dry graphite. Dry sand may be used on small fires. Not advisable to use sand around machinery. Do not use water, foam, carbon tetrachloride, or carbon dioxide.
Magnesium Alloys (high percentage of magnesium)		
	Protect eyes and skin from flying particles in case of fire.	Smother with an excess of dry graphite. Dry sand may be used on small fires. Not advisable to use sand around machinery. Do not use water, foam, carbon tetrachloride, or carbon dioxide.

Fire Hazard	Storage
	ious corrosion of sprinkler piping and heads.
None.	Safeguard against mechanical injury.
Oxidizing liquid. May cause ignition of combustible material if left standing in contact with it. May decompose violently if contaminated with iron, copper, chromium, and most metals or their salts.	Store in a cool place in ventilated containers remote from combustible material and catalytic metals such as iron, copper, chromium.
Flammable gas. Forms flammable and explosive mixture with air or oxygen. Explosive range in air (upward propagation) 4.3 (low limit) to 46. Heavier than air. Specific gravity 1.19 (air = 1). Ignition temperature 346°-379° C. (655°-714° F.)	Store in ventilated place away from fuming nitric acid and oxidizing materials. Encountered in chemical laboratories, metallurgical and smelting works, gas works, sewers.
Oxidizing material. Classes with sodium nitrate.	Isolate; safeguard against mechanical injury.
Combustible, particularly in the form of powder, shavings, or thin sheets. When powder is disseminated in the air, explodes by spark. In finely divided form liberates hydrogen in contact with water. In massive form (ingots or blocks) comparatively difficult to ignite.	Store remote from water or moisture, oxidizing materials, chlorine, bromine, iodine, acids, and alkalies.
In compact or bulk form (castings, plates, etc.) difficult to ignite. Readily combustible in form of dust, turnings, and hazardous in such form with chlorine, bromine, iodine, oxidizing agents, acids, and alkalies.	Store dust, shavings, and turnings in metal containers in detached building or fire-resistive room. Detailed safety precautions for handling are usually supplied by manufacturers of magnesium alloys.

10687

Usual Shipping Container	Life Hazard	Fire Fighting Phases
Magnesium Nitrate		
Wooden boxes.		See sodium nitrate.
Muriatic Acid — *See Hydrochloric Acid.*		
Naphthalene		
Tins, barrels, and burlap bags.	Irritant. Slight narcotic effect on the skin. The hot vapors produce itching, pain, and eczema.	Water is the best extinguishing agent. Foam or water applied to molten naphthalene at temperatures over 230° F. will cause foaming.
Nickel Nitrate		
Wooden kegs.	Poisonous when taken internally.	
Nitric Acid		
Carboys and glass bottles.	Corrosive; causes severe burns by contact; deadly if inhaled.	
Nitraniline or Nitro Aniline		
Wooden kegs.	Poisonous.	
Nitrochloro-Benzene		
Wooden kegs.	Serious under fire conditions.	
Phenol		
	Poisonous.	
Phosphorus, Red		
Hermetically sealed tin cans inside of wooden boxes.	Yields toxic fumes when burning.	Flood with water, and when fire is extinguished cover with wet sand or dirt. Under certain conditions at high temperatures reverts to white phosphorus.
Phosphorus, White, (or Yellow)		
Under water usually in hermetically sealed cans enclosed in other hermetically sealed cans with outside wooden boxes, or in drums or tank cars.	Poisonous. Serious under fire conditions. Yields highly toxic fumes when burning. Contact of phosphorus with the skin causes severe burns.	Deluge with water until fire is extinguished and phosphorus solidified; then cover with wet sand or dirt.

HAZARDOUS CHEMICALS

Fire Hazard	Storage
Oxidizing material. Classes with sodium nitrate.	See sodium nitrate.
Gives off flammable vapors when heated. Flash point 176° F. Naphthalene dust forms explosive mixtures with air. Ignition temperature 559° C. (1038° F.).	Isolate; keep away from fire or heat.
Oxidizing material. Classes with sodium nitrate.	Safeguard against mechanical injury.
May cause ignition when in contact with combustible materials; corrodes iron or steel; may cause explosion when in contact with hydrogen sulfide and certain other chemicals.	Safeguard against mechanical injury of containers; isolate from turpentine, combustible materials, carbides, metallic powders, fulminates, picrates or chlorates.
In presence of moisture causes nitration of organic materials and may result in spontaneous ignition.	Store in dry place; safeguard against mechanical injury.
Gives off flammable vapors when heated, which may form explosive mixtures with air.	Isolate, preferably in the open; if inside should be in unheated compartment or building.
When heated yields flammable vapors. Flash point 172.4° F.	Soluble in water. Never store with or above food products.
Flammable. Explosive when mixed with oxidizing materials. Not as dangerous to handle as white phosphorus, and when afire, more readily extinguished.	Isolate from other chemicals; safeguard against mechanical injury of container.
Highly flammable. Explosive in contact with oxidizing material. Ignites spontaneously on contact with air.	Isolate from chemicals. Store large quantities under water in underground iron or concrete tanks.

Usual Shipping Container	Life Hazard	Fire Fighting Phases
Phosphorus Sesquisulfide, P_2S_5		
Wooden boxes, iron drums, glass bottles.	Fumes in fire toxic.	
Picric Acid		
Wooden kegs, boxes, bottles.	Classes with high explosives in respect to life hazard.	
Potassium (Metallic Potassium)		
Hermetically sealed steel drums, tin cans, and tank cars.	Strong caustic reaction. Dangerous.	Smother with an excess of dry graphite or dry sand. Do not use water. It is difficult to extinguish fires in large quantities of potassium.
Potassium Chlorate		
Wooden barrels or kegs.	Dangerous under fire conditions.	Water is the best extinguishing agent.
Potassium Cyanide		
Tightly closed glass, earthenware, or metal containers; wooden boxes with inside metal containers, or with hermetically-sealed metal lining; metal barrels or drums.	Highly poisonous when taken internally. Evolves hydrocyanic acid gas (poisonous) on contact with acids or moisture.	
Potassium Hydroxide		
Wooden barrels, glass bottles.		
Potassium Nitrate		
Bags, tins and glass bottles.		See sodium nitrate.
Potassium Perchlorate		
Paper-lined metal containers.		Use water to prevent the spread of fire.
Potassium Permanganate		
Tins.		

HAZARDOUS CHEMICALS

Fire Hazard	Storage
Highly flammable. Ignites by friction.	Isolate from chemicals. Safeguard container against shock.
Flammable, explosive. Oxidizing material.	Isolate or store under water, keep away from other material, including metals, with which it forms sensitive and explosive picrates.
Oxidizes rapidly on exposure to atmosphere, igniting spontaneously if warm enough. Water is decomposed suddenly by contact with potassium, sufficient heat being generated to ignite spontaneously the evolved hydrogen (in the presence of air). Its reaction with water is more violent than that of sodium.	Do not tier if it can be avoided. Keep away from water, avoiding sprinkler systems. Safeguard against mechanical injury of containers.
Oxidizing material; explosive when in contact with combustible material.	Isolate from combustible material, acids, and sulfur.
Cyanides not flammable but evolve hydrocyanic acid (see) on contact with acids or moisture.	Isolate. Safeguard containers against mechanical injury.
Generates heat on contact with water. Classes with calcium oxide (lime) in hazard.	Store in dry place; keep remote from water or moisture.
In contact with organic materials causes violent combustion on ignition. Classes with sodium nitrate.	Store in dry place, prevent contact with organic material.
Oxidizing material. Combustible in contact with organic materials. More stable than chlorates. Explosive in contact with concentrated sulfuric acid.	Store in dry place away from acids and combustible material.
Oxidizing material. Explosive when treated with sulfuric acid, and in contact with alcohol, ether, flammable gases, and combustible materials.	Isolate from other chemicals, especially those noted under fire hazard.

Usual Shipping Container	Life Hazard	Fire Fighting Phases
Potassium Peroxide Tins and steel drums.	Strong caustic reaction and dangerous under fire conditions. Avoid breathing dust in handling, and wear goggles to protect eyes.	Smother with dry sand, soda ash, or rock dust. Do not use water.
Potassium Persulfate Glass bottles and stone jars.		
Potassium Sulfide Iron drums, cans, glass bottles.	Yields irritating and corrosive gases when burning.	
Salicylic Acid Bottles, cartons, kegs and barrels.	Used in manufacture of aspirin, salol, and methyl salicylate; also in manufacture of azo dyes. Preservative. There have been explosions in sublimation chambers.	Slightly soluble in water. Extinguish with water or smother with carbon dioxide or sand.
Saltpeter — *See Potassium Nitrate.*		
Silver Nitrate Amber or black glass bottles.	Corrosive and poisonous.	
Soda, Caustic — *See Sodium Hydroxide.*		
Sodium Hermetically sealed steel drums, tin cans, and tank cars.	Strong caustic reaction. Dangerous.	Smother with an excess of dry graphite or dry sand. Do not use water. It is difficult to extinguish fires in large quantities of sodium.
Sodium Chlorate Wooden barrels, glass bottles.	See potassium chlorate.	See potassium chlorate.
Sodium Chlorite ($NaClO_2$) Wooden boxes with inside containers which	Poisonous when taken internally. Dangerous	Soluble in water. Water is best extinguishing agent.

	Fire Hazard	Storage
	Does not burn or explode *per se* but mixtures of potassium peroxide and combustible substances are explosive and ignite easily even by friction or on contact with a small amount of water. Reacts vigorously with water and in large quantities this reaction may be explosive.	Store remote from organic substances and water. Do not expose to sprinkler systems.
	Oxidizing material. May cause explosion in a fire.	Keep dry; safeguard against mechanical injury of contain-
	Moderately flammable, yields flammable hydrogen sulfide on contact with mineral acids and sulfur dioxide when burning.	Safeguard against mechanical injury of containers.
	Combustible solid. Flash point 157° C. (315° F.). Ignition temperature 545° C. (1013° F.). Salicylic dust forms explosive mixtures with air.	Store in dry place.
	Oxidizing material.	Store in dark place; keep cool and away from combustible material.
	Water is suddenly decomposed by contact with sodium with the evolution of hydrogen, which may ignite spontaneously (in the presence of air). Classes with potassium in respect to fire hazard but its reaction with water is less violent than that of potassium.	Do not tier if it can be avoided. Keep away from water, avoiding sprinkler systems. Safeguard against mechanical injury of containers.
	Oxidizing material. Classes with potassium chlorate. See potassium chlorate.	See potassium chlorate.
	Strong oxidizing material. Decomposes with evolution of heat at about 175° C. (347° F.). Ex-	Isolate from combustible material, sulfur, and acids.

Usual Shipping Container	Life Hazard	Fire Fighting Phases
Sodium Chlorite ($NaClO_2$) (*Continued*)		
must be glass or earthenware not over 2¼ lb. capacity, or metal not over 5 lb. capacity each.	under fire conditions. Used in bleaching textiles and paper.	
Sodium Cyanide— ***See Potassium Cyanide.***		
Sodium Hydrosulfite Wooden barrels, kegs, or boxes with inside glass bottles of capacity not exceeding 5 lb. each, or metal containers.	Bleaching agent for removing dyes.	Smother with sand or foam.
Sodium Hydroxide Iron drums.		
Sodium Nitrate Bags, tins and glass bottles.		Most fires involving sodium nitrate can safely be fought with water in the early stages; at such times it should be flooded with water. When large quantities are involved in the fire, the sodium nitrate may fuse or melt, in which condition application of water may result in extensive scattering of the molten material, and, therefore, care should be taken in applying water to the material after fire has been burning for some time.
Sodium Perchlorate Paper-lined metal containers.		See potassium perchlorate.
Sodium Peroxide — *See Potassium Peroxide.*		
Sodium Sulfide Iron drums and bottles.	See potassium sulfide.	

	Fire Hazard	Storage
	plosive in contact with combustible material. See potassium chlorate. In contact with strong acid liberates chlorine dioxide, an extra hazardous gas.	
	Combustible. Heats spontaneously in contact with moisture and air, and may ignite nearby combustible material.	Store in dry place away from combustible materials.
	Classes with potassium hydroxide and calcium oxide.	Isolate from heat and water. See calcium oxide and potassium hydroxide.
	Oxidizing material. Bags or barrels may become impregnated with nitrate, in which condition they are readily ignitable. In contact with organic or other readily oxidizable (combustible) substances it will cause violent combustion on ignition.	Store in dry place; prevent contact with organic or combustible material. Fire hazard less if removed from bags and stored in noncombustible bins.
	See potassium perchlorate.	See potassium perchlorate. Sodium perchlorate in anhydrous form is very hygroscopic and not used much in industries.
	Moderately flammable. Classes with potassium sulfide.	See potassium sulfide.

A TABLE OF COMMON

Usual Shipping Container	Life Hazard	Fire Fighting Phases
Strontium Nitrate Barrels and boxes.		See sodium nitrate.
Strontium Peroxide (SrO_2) Metal cans.		Smother with sand, ashes, or rock dust. Do not use water.
Sulfur Sacks, boxes, barrels and box cars.	When burning forms sulfur dioxide, which in concentrations of 0.2% by volume in air may cause serious injury in ½ hour or less.	Water in form of spray best extinguisher. Small fires may be smothered with sand or additional sulfur. (Sulfur dioxide does not support combustion.) Avoid use of pressure hose (solid) streams, and do not scatter sulfur dust. If spray nozzle is not available, water may be allowed to flow out of hose (without nozzle) on to a burning pool of sulfur, or saturated steam may be used. See N. F. P. A. Code for the Prevention of Sulfur Dust Explosions and Fires.
Sulfuric Acid Carboys, iron drums, glass bottles and tank cars.	Corrosive; dangerous fumes under fire conditions.	Smother with sand, ashes, or rock dust, but avoid water.
Thorium Nitrate Wooden kegs.		See sodium nitrate.
Uranium Nitrate Glass bottles, boxes.		
Vinyl Ether Glass bottles and metal cans.	Anaesthetic.	Lighter than water (Sp. gr. 0.774). Not soluble in water. Water may be used only to cool metal containers. Best extinguishing agents are carbon dioxide, sand, and carbon tetrachloride.

HAZARDOUS CHEMICALS

Fire Hazard	Storage
Oxidizing material. Classes with sodium nitrate.	Safeguard against mechanical injury; keep away from other materials.
Oxidizing material. Hazards in class with barium peroxide.	Store in dry place away from combustible materials.
Flammable. Dust or vapor forms explosive mixtures with air. Hazardous in contact with oxidizing material.	Provide good ventilation. Isolate from chlorates, nitrates and other oxidizing materials.
May cause ignition by contact with combustible materials. Corrodes metal.	Safeguard against mechanical injury, isolate from saltpeter, metallic powders, carbides, picrates, fulminates, chlorates and combustible materials.
Oxidizing material. Classes with sodium nitrate.	Store in dry place, remote from water or moisture.
Oxidizing material. Classes with sodium nitrate.	See sodium nitrate.
Highly volatile flammable liquid. Flash point below −22° F. Gives off even at comparatively low temperatures vapors which form flammable mixtures with air or oxygen. Explosive range 1.70% to 27.0% (upward propagation). Hazard in a class with ethyl ether. Only electrical equipment of the explosion-proof type, Group C classification tentative pending further tests, permitted in atmospheres containing vinyl ether vapor in flammable proportions.	Isolate. Safeguard containers against mechanical injury Store in a cool, well ventilated storeroom.

Usual Shipping Container	Life Hazard	Fire Fighting Phases
Zinc Chlorate		
Glass bottles, in drums.	Serious under fire conditions.	
Zinc Powder or Dust		
Cartons, wooden barrels, or steel drums.	Zinc is comparatively volatile at elevated temperatures. Under fire conditions precautions should be taken to avoid breathing fumes, which may cause metal fume fever.	Smother with sand, ashes, or rock dust. Do not use water.
Zirconium		
Wooden kegs, glass bottles.		Available data, indicate fires can be controlled by foam or sand. Carbon tetrachloride, carbon dioxide, soda and acid extinguishers ineffective.

HAZARDOUS CHEMICALS

Fire Hazard	Storage
When in contact with organic material explodes by slight friction, percussion or shock. Classes with potassium chlorate.	Safeguard against mechanical injury; avoid tiering; isolate.
Hydrogen is evolved when commercial zinc is in contact with acids, sodium hydroxide, or potassium hydroxide. Hydrogen also evolved by acid-forming combinations containing zinc, such as zinc chloride and moisture. Dust may form explosive mixtures with air. Zinc dust in bulk in a damp state may heat and ignite spontaneously on exposure to the air.	Store in dry, ventilated place away from water or moisture. Isolate from acids.
Has comparatively low ignition temperature. Highly flammable in dry state. Burns with intensely brilliant flame. Explosive in contact with oxidizing agents. Powder very susceptible to ignition by static electricity, and explosion may be caused when disbursed into a cloud in air by static charges generated.	Encountered in granular, finely divided powder; also in form of small, friable, spongy lumps. Store only in wet condition and in small quantities. Isolate from oxidizing materials.

PROPERTIES OF FLAMMABLE LIQUIDS, GASES, AND SOLIDS

Copyright 1940 by Inspection Department, Associated Factory Mutual Fire Ins. Cos., and reprinted with permission.

The following table gives pertinent data as to the fire hazard of liquids, gases, and solids found in industrial plants. It has been assembled from the results of tests made by the Factory Mutual Laboratories and from other data carefully chosen as the most reliable.

Abbreviations and Symbols

The following abbreviations are not used in the alphabetical listing but are shown with some names to identify the compound exactly.

o, ortho	*p*, para	
m, meta	*prim*, primary	*sym*, symmetrical
n, normal	*sec*, secondary	*ter*, tertiary

The numerical prefixes mono-, di-, tri-, and tetra- will be found in regular alphabetical order.

d., decomposes	sub., sublimes
>, greater than	<, less than

* An asterisk following the name of a metal indicates that hydrogen will be liberated when the metal is in contact with water. With the exception of potassium and sodium, hydrogen will be liberated in hazardous quantities only if the metal is in a finely divided form.

The properties of asphalts, naphthas, and oils vary over a large range as indicated. When it is necessary to know the exact hazard of a material, a sample should be sent to the Factory Mutual Laboratories at 184 High St., Boston, Mass., for test.

Flash Point. The approximate closed-cup flash points of hydrocarbons (organic compounds composed of only carbon and hydrogen) may be determined by the use of the following formula:

$$\textit{Closed cup flash point } °F. = 0.73 \times [\textit{initial}] \textit{ boiling point } °F. - 122$$

For petroleum and coal-tar distillates, the formula is applicable between initial boiling points of −150° F. and +550° F.

Explosive Limits. The data given for the lower and upper explosive limits are, with few exceptions, the values for upward flame propagation through a cylindrical tube.

Vapor Densities for the most part, have been calculated.

Suitable Extinguishing Agents. The code numbers in the last column indicate the following extinguishing agents.

1 Water (See note below)	4 Dry chemical
2 Foam	5 Powdered talc
3 Carbon dioxide	

Note: Water discharged from spray nozzles behaves much differently from water discharged from sprinklers or hose streams. The finely divided drops from a spray nozzle absorb much more heat than an equal volume of water from a sprinkler or hose stream and also partially smother the fire by excluding air. In general, water spray nozzles are suitable for use on fires in flammable liquids having a flash point over 150° F., but before purchasing new equipment, consult your Insurance Company or the Inspection Department.

If either water or foam is applied to a body of flammable liquid, all of which is heated above 250° F., the hot liquid may foam over and spread the fire.

I.C.C. Shipping Labels

Red —Flammable liquids with flash points at or below 80° F. and flammable compressed gases.

Yellow—Flammable solids (except explosives) and oxidizing materials (chlorates, permanganates, peroxides, nitrates).

White —Corrosive liquids (mineral acids).

Green —Non-flammable compressed gases.

Labels are required only for interstate shipments or for intrastate shipments by common carrier engaged in interstate or foreign commerce. Absence of a label does not necessarily mean that the material is non-hazardous.

MODERN CONCEPTS OF MATTER

By Helen M. Davis, *Science News Letter*, October 6, 1945.
Reprinted by permission.

1. A single ATOM is the tiniest particle of any chemical element that can exist by itself and retain the qualities that mark it as that element.

2. All material things in the universe known to our senses are composed of one or more CHEMICAL ELEMENTS.

3. Substances composed of more than one element are known as COMPOUNDS. Atoms of elements are held together in compounds by electrical forces in the outer parts of their structure.

4. The smallest unit of a compound, usually composed of two or more atoms, is known as a MOLECULE.

5. There used to be 92 chemical elements, from hydrogen ($_1H^1$) the lightest, to uranium ($_{92}U^{238}$), the heaviest. There are now two new elements, NEPTUNIUM ($_{93}Np^{239}$) and PLUTONIUM ($_{94}Pu^{239}$).

6. When elements are represented, as above, by their chemical SYMBOLS, the subscript number is the atomic number. This is different for each element. The superscript number represents the atomic weight.

7. One of the qualities characteristic of matter is weight or mass. ATOMIC WEIGHT is expressed on a relative scale, as compared with the weight of hydrogen which is taken as one.

8. ATOMIC NUMBER is the measure of the electric charge on the nucleus of the atom. Atomic weight is the measure of the atom's mass.

9. Different samples of the same element, when tested by chemists, are sometimes found to have different atomic weights. Lead which occurs with radium, for example, has a different atomic weight from ordinary lead.

10. In all other ways the two kinds of lead are chemical twins, exactly alike except for weight. Elements which differ in weight only are called ISOTOPES.

11. Uranium has several isotopes. The usual kind, whose atomic weight is 238, was used to produce the two new elements. U-235 was used to make the ATOMIC BOMB.

12. Each of the new elements, neptunium and plutonium, has two isotopes whose atomic weights are 238 and 239.

13. Different elements, quite distinct in chemical behavior, may have the same atomic weight. We have $_{92}$U-238, and $_{93}$Np-238, and $_{94}$Pu-238, all with different properties. Such elements are now called ISOBARS.

14. All atoms are composed of standard interchangeable parts. These are PROTONS, NEUTRONS and ELECTRONS.

15. Protons and neutrons make up the NUCLEUS of the atom. The structure of the atom is much like that of the solar system. The nucleus corresponds to the sun at the center. The planets are electrons.

16. The proton and the neutron each have a mass about equal to that of a hydrogen atom, which is 1 on the chemist's scale. Each is about 1800 times heavier than the electron.

17. The ELECTRONS, light in weight and some distance away from the heart or nucleus of the atom, revolve around the nucleus much as planets revolve around the sun. They are held in their courses by electric attraction.

18. The proton has a POSITIVE charge of electricity, the electron has a NEGATIVE charge equal and opposite to the positive charge of the proton. The neutron has no charge at all.

19. The difference in chemical properties of the elements is caused by difference in the number of protons in the nucleus. This is the ATOMIC NUMBER.

20. Atomic Weight is the SUM of the weights of the protons and neutrons in the nucleus.

21. It is the NEUTRON which figures in the transmutations which give atomic power. Neptunium and plutonium were formed by bombarding uranium 238 with neutrons.

22. Neutrons can PENETRATE to the nucleus of heavy atoms when charged particles would be repelled by charges in the atom.

23. The HYDROGEN atom is believed to have just one proton as its nucleus, with one electron circling around it. Hydrogen's atomic weight and atomic number are each one.

24. Hydrogen has one isotope which is just like ordinary hydrogen except that it is twice as heavy. It is known as "heavy hydrogen" and sometimes as DEUTERIUM. Its compound with oxygen is called "heavy water".

25. The nucleus of HEAVY HYDROGEN contains one proton and one neutron. The atomic number of heavy hydrogen is one, corresponding to one proton. The atomic weight is two, corresponding to the two heavy particles, proton and neutron.

26. HELIUM has two protons and two neutrons in its nucleus. The two protons correspond to helium's atomic number two. The combined weights of protons and neutrons in the nucleus give helium its atomic weight 4. Two electrons, held in their orbits by the two protons, revolve around the nucleus.

27. The VOLUME of an atom is determined by the orbits of its outermost revolving electrons. Only a small fraction of the size of an atom is actually occupied by the protons, neutrons and electrons, just as the space occupied by the sun, the earth and other planets is only a small part of our solar system.

28. In spite of all the unoccupied SPACE, an atom is quite IMPENETRABLE to other atoms and to larger bodies. The electrons revolve millions of times a second, and keep everything out of the space within quite as effectively as though they were everywhere at once.

29. The only things that can get inside an atom are smaller things, FRAGMENTS of other atoms, protons, neutrons or electrons. They must be shot with just the right speed. These fragments of atoms are observed as radiations given off by radio-active elements which are breaking up spontaneously.

30. RADIATION is wave motion, known to us as the electro-magnetic waves used for radio transmission, heat, light, X-rays and cosmic rays. Large numbers of extremely tiny particles in motion together act like waves.

31. Three types of radiation are given off by radio-active substances. ALPHA particles are high-speed nuclei of helium atoms. BETA particles are high-speed electrons. GAMMA rays are electromagnetic radiations similar to X-rays and light.

32. Of these, only the gamma rays are properly called radiations, and even these act very much like particles because of their short wave-length. Such a "particle" or quantum of gamma radiation is called a PHOTON.

33. In general, the gamma rays are very penetrating, the alpha and beta rays less so. Even though the alpha and beta rays are not very penetrating, they have enormous SPEED.

34. The speed with which atom particles travel is the source of atomic energy. ENERGY is capacity to do work. It is work stored up for future use.

35. If you raise a weight to a height above the ground and suspend it there by some device, the WORK you put into raising it can be stored there indefinitely as POTENTIAL ENERGY. It will be there, ready, whenever you decide to release it.

36. The energy which a moving body has because it is in motion is called KINETIC ENERGY. The kinetic energy of any particle depends upon its mass and the square of its velocity. Energy is conserved by the moving particle until it strikes an object, then work is done.

37. All ENERGY is either potential or kinetic. Either one can be converted into the other. These two conversions are continually occurring.

38. Particles of atomic size have kinetic energy arising from several different kinds of MOTION. All atoms are constantly in motion.

39. If the atoms are so dispersed that the material constituting them is a GAS, that gas will exert pressure on all sides of the container that holds it. If the container is a balloon bag, the imprisoned gas can do work by lifting heavy weights into the air.

40. Atoms which compose an element that will combine readily with another element, as hydrogen or carbon will combine with oxygen, have unsymmetrical arrangements of the outer electrons in their systems. These unsymmetrical arrangements tend to set up a sort of strain, which causes CHEMICAL COMBINATION to take place when elements with suitable combining powers are brought together.

41. These unsymmetrical arrangements give rise to FORCES which result in kinetic energy. This energy appears, for example, when carbon and oxygen burn to carbon dioxide, giving off heat, or hydrogen and oxygen explode to form water, again giving off heat.

42. Chemicals combining to form stable compounds give off energy in the process. These are known as EXOTHERMIC REACTIONS. Combinations which absorb energy, forming unstable compounds, are known as ENDOTHERMIC REACTIONS. Explosives, for example, which are highly unstable, are formed by endothermic reactions.

43. Chemical forces, electricity and heat are all forms of energy. Potential and kinetic energy may be distinguished in each case.

44. These energies all arise from motion of the atom as a whole, or motion resulting from attractions and repulsions between the outer PLANETARY ELECTRONS of the atom's structure.

45. Energy resulting from motion of particles deep within the structure of the atom was unknown until the discovery of RADIOACTIVITY.

46. Radioactive elements undergo SPONTANEOUS breaking up of their atoms, giving off alpha and beta particles and gamma rays. Loss of these particles causes the radio-active elements to change into other elements.

47. The energies shown in these TRANSFORMATIONS are thousands of times greater than the kinetic energies which the molecules of a gas have by reason of their motion when heated. They are thousands of times greater than the energy changes per atom in chemical reactions.

48. The property of matter that connects it with motion is INERTIA. Inertia is opposition to change of motion.

49. One conclusion that appeared early in the development of the theory of RELATIVITY was that the mass due to inertia of a moving body increases as its speed is increased.

50. This increase implied an equivalence between an increase in energy of motion of a body (kinetic energy) and an increase in its MASS.

51. It was for this reason that Einstein suggested that studies of radioactivity might show the EQUIVALENCE of mass and energy.

52. Einstein's statement is that the amount of energy, E, equivalent to a mass, m, is given by the equation $E = mc^2$ where c is the VELOCITY OF LIGHT.

53. From this equation, one kilogram (2.2 pounds) of matter, if converted ENTIRELY into energy, would give 25 billion kilowatt hours of energy. This is equal to the energy that would be generated by the total electric power industry in the United States (as of 1939) running for approximately two months.

54. Compare this fantastic figure with the 8.5 kilowatt hours of heat energy which may be produced by BURNING an equal amount of coal.

55. Until the atomic power research program, no instance was known of matter being converted into energy without more energy being used to produce the transformation than was released by it.

56. Two axioms of physics stated: (1) MATTER can be neither created nor destroyed; (2) ENERGY can be neither created nor destroyed. For all practical purposes they were true and separate principles until about 1940.

57. It is now known that they are, in fact, two phases of a single principle, for we have discovered that energy may sometimes be CONVERTED into matter and matter into energy.

58. Such conversion is observed in the phenomenon of nuclear FISSION of uranium, a process in which atomic nuclei split into fragments with the release of an enormous amount of energy.

59. The extreme size of the CONVERSION FACTOR explains why the equivalence of mass and energy is never observed in ordinary chemical combustion.

60. We now believe that the heat given off in such COMBUSTION has mass associated with it, but this mass is so small that it cannot be detected by the most sensitive balances available.

61. Transformation of matter into energy is an entirely different sort of phenomenon than the usual chemical transformations, where the matter is changed into a different form but its MASS persists.

62. From the standpoint of the Laws of the Conservation of Matter and of Energy alone, transformation of matter into energy results in the DESTRUCTION of matter and CREATION of energy.

63. The OPPOSITE transformation, which astronomers believe may be going on in some of the stars, amounts to the destruction of energy and the creation of matter.

64. It is difficult for us to imagine the reconciliation of two such different concepts as matter, with its characteristic mass or weight, and energy, which does not have this quality. We shall, perhaps, be forced to think of the stuff of the universe as some such combination of matter and energy as would be symbolized by the coined word "MATTERGY"

THE EARTH

Age: Based on analysis of lead isotopes in meteoric and oceanic minerals, the age of the earth is estimated to be 4.6 billion years, a value in agreement with most astronomical findings. *Chem. & Eng. News*, 31, 4874 (1953).

Dimensions: Distance from the sun (average), 92,900,000 ±100,000 miles. Diameter, *ca* 7,900 miles. Circumference, *ca* 25,000 miles. Surface area, *ca* 197,000,000 square miles. Specific gravity, (mean) 5.6; (at center) 11.2.

Composition: According to F. W. Clark, the relative proportions by weight are: *lithosphere* (the earth's crust to a depth of 10 miles), 93.06%; *hydrosphere*, 6.91%; *atmosphere*, 0.03%.

Atmosphere: The atmosphere has been divided into layers with various names used to characterize different regions. In a classification based on composition, the *homosphere* is the region up to about 100 km (62 mi) where composition first begins to change materially; the *heterosphere* is the region beyond this where there is a different composition due to diffusion and molecular dissociation. In geophysics the classification into layers is on a basis of temperature; these layers are: *troposphere*, 0–11 km (0–7 mi); *stratosphere*, 11–35 km (7–22 mi); *mesosphere*, 35–80 km (22–50 mi); *thermosphere*, 80–400 km (50–250 mi); *exosphere*, beyond 400 km (250 mi). The boundary regions for these layers are, respectively, *tropopause*, *stratopause*, *mesopause*, and *thermopause* or "*critical level*." The extent of the layers as given above are averages for latitude 45° north or south. The heights vary with the seasons, the latitude and atmospheric conditions. The term *upper atmosphere* is used by weather forecasters to describe the upper troposphere, whereas the radio engineer and others use it to mean regions above the stratosphere. Other names have been used to characterize regions of the atmosphere such as: *ozonosphere* (18–30 km; 11–19 mi) for the level where ozone concentration is greatest; *chemosphere* (30–80 km; 19–50 mi) for the region where ions are formed by action of solar radiation upon atmospheric components.

THE ELEMENTS

ACTINIUM (Gr. *aktis*, ray). Ger. *Aktinium*. Fr. *actinium*. A radioactive element discovered in 1900 by Debierne in pitchblende. Actinium has not yet been isolated nor have any of its salts been prepared in a pure state, but always contaminated by thorium and the rare earths. It is element No. 89 in the periodic table and the first element in the actinide series which includes elements 89 through 101. Actinium is constantly breaking down into actinium-X, which in turn breaks down until actinium-D, the end product, is formed. Actinium is always associated with uranium and radium in nature and for every 1000 kilograms of uranium there are 0.34 grams of radium and only about 0.06 milligrams of actinium. It is very difficult to separate actinium from lanthanum, and, according to Mme. Curie, the preparation of pure actinium salts does not appear imminent.

ALUMINUM (L. *alumen*, substance having an astringent taste). Ger. *Aluminium*. Fr. *aluminium*. Aluminum is a light, silvery metal, very malleable and ductile. Lavoisier predicted in 1782 that alumina was the oxide of a metal not then known. The first isolation of the metal is usually credited to Wöhler who in 1827 obtained the element by heating aluminum chloride with metallic potassium. Recent search of the early literature discloses, however, that the discovery should really be credited to Oerstedt, a Dane, who in 1825 heated aluminum chloride with a 1.5% potassium mercury amalgam and thus obtained the first metallic aluminum. The commercial method of isolation of the metal by electrolyzing a solution of the oxide in fused cryolite is based upon the work of Hall. Aluminum does not occur in the free state but its compounds are very widely distributed, aluminum being the most abundant metal. Cast aluminum is about as hard as silver. The metal takes a high polish but tends to become coated with a film of oxide. Although soluble in dilute HCl or H_2SO_4 and in solutions of KOH or NaOH, it is practically insoluble in HNO_3 or acetic acid even when hot. It is a very important metal being widely used in electrical transmission, since its conductivity per pound is greater than that of copper. Light alloys containing aluminum are used in making parts for automobiles, motorcycles and aircraft. About 70% of the frames and 25% of the engines and propellers of military aircraft are made of aluminum. It is also used in counter-radar in the form of foil, two ounces being made to appear on radar screens like an entire bomber. It is used in making cooking utensils, chemical apparatus, etc. In metallurgy aluminum is used as a degasifier, while aluminum powder is used in certain explosives, as a flashlight powder, in aluminum paints, and in the laboratory as a reducing agent. The thermite process is one that uses large amounts of aluminum. Cement, one of the most important building materials, is made up largely of aluminum silicate. Al_2O_3 or alumina, $Al_2(SO_4)_3$, $AlCl_3$ and $Al(NO_3)_3$ are typical aluminum compounds. The price is about 21½¢ per pound (47¢ per kilogram).

AMERICIUM (from America, where it was first produced). This is one of the trans-uranium elements (No. 95) produced by the research on atomic fission. Seaborg, James, Morgan, Ghiorso, Hamilton and others produced this element by the action of helium ions of very high energy on uranium. It is now believed that Pu-241 is first formed and this breaks down by beta-emission to form Am-241. This isotope has a half-life of 500 years with 7 billion alpha disintegrations per minute per milligram. In its electronic configuration americium bears the same relation to actinium as europium does to lanthanum. As would be expected, americium has a very stable tri-valent state and resists oxidation under conditions which would produce higher valencies with uranium, neptunium, or plutonium but, unlike europium, it is possible to oxidize it to the pentavalent state. Americium is usually prepared in the clyclotron by the action of alpha particles on U-238 or Pu-239. The free element has been produced as a silvery metal by the action of barium

vapor on AmF_3. The dioxide, AmO_2, the monoxide, AmO, the chloride, $AmCl_3$, and the other tri-halides have been prepared.

ANTIMONY (Gr. *antimonos*, opposed to solitude, as antimony is always associated with other minerals). Ger. *Antimon*. Fr. *antimoine*. Antimony compounds have been known from ancient times, although the metal was probably confused with lead. Antimony was known to Georgius Agricola in the 16th century, to Libavius in 1615, and to one Basil Valentine, probably the pseudonym of one or more adepts who lived in the 15th or 16th century, whose works in Dutch and Latin were published from 1609 to 1676. Native antimony is known, but it is too rare to be commercially important. The ores of antimony are the sulfides and various antimonides and sulfantimonides of the heavy metals. The most important ore is stibnite, Sb_2S_3. The method of extraction used with this ore is the iron reduction process, which involves fusing the ore with iron turnings or shavings and slagging off the resulting iron sulfide with sodium chloride or sodium sulfate. The ordinary form of antimony is the metallic or gray variety. An unstable yellow antimony corresponding to yellow arsenic has been made. Black antimony is amorphous and is more active and more easily volatilized than metallic antimony. Electrolytic antimony, deposited by a weak current from an HCl solution of $SbCl_3$, is known as explosive antimony. This form has also been made in other ways; it explodes when scratched, when touched with a red-hot wire, or when heated to 125°C. Many antimony salts are poisonous but the metal is not. Antimony is used in making many important alloys such as bearing metal, type metal, hard lead, pewter, etc., chiefly for its property of hardening the softer metals. Its compounds are used in making pigments, in pharmaceutical preparations, as a mordant, in making percussion caps, fireworks and signal lights, and in the preparation of certain aniline dyes. A few common antimony compounds are $SbCl_3$, Sb_2O_3, SbH_3 or stibine, Sb_2O_5, and Sb_2S_3. The price of the metal is about 29¢ per pound (64¢ per kilogram).

ARGON (Gr. *argos*, neutral, inactive). Ger. *Argon*, Fr. *argon*. A colorless, odorless gas, somewhat heavier than air. It was discovered in 1894 by Lord Rayleigh and W. Ramsay, but over a century before Cavendish had found that air contained about 1/120th part of some gas other than oxygen, nitrogen and carbon dioxide. This small part was later proved to be mostly argon. Each square mile of the earth's surface supports about 800,000,000 pounds of argon. The gas is seldom prepared pure, it being sufficient in most cases to remove oxygen, nitrogen and carbon dioxide, leaving argon and traces of the rare inert gases. These can be removed by several fractional distillations of liquid air. Argon and the other inert gases are used to fill incandescent and fluorescent light bulbs as well as various radio and rectifier tubes. A cylinder holding 200 cubic feet (5663 liters) of 99.6% argon at normal pressure can be refilled for about $30.

ARSENIC (Gr. *arsenicos*, valiant or bold, from its action on other metals. L. *arsenicum*, yellow orpiment). Ger. *Arsen*. Fr. *arsenic*. Arsenic and its compounds have been known from ancient times, the metal being found in the free state as well as combined. Arsenic occurs as metallic arsenic, which is steel gray, opaque, and conducts electricity; as yellow arsenic, which is translucent and a non-conductor; as gray arsenic, which is gray to black, translucent and a non-conductor; and as brown arsenic, which is a pale reddish brown, opaque, amorphous, and a non-conductor of electricity. The yellow form is very unstable, it being necessary to keep it very cold and in the dark. The ores of arsenic are the two sulfides As_2S_3 and As_2S_5, FeAsS, and various arsenides and arsenates. It is usually prepared by heating FeAsS or $FeAs_2$ in the absence of air, whereupon the arsenic sublimes. It is also obtained by treating ores from tin, copper, and tungsten mines. The compounds of arsenic in general are deadly poisons but some are used in medicine, usually as a tonic. The natives of certain parts of Europe take large doses of As_2O_3, enough to be fatal to one not habituated, in the belief that their endurance is increased. Certain organic

arsenic compounds such as salvarsan are important remedial agents, having specific power against blood parasites with little damage to the host when properly administered. The metal is used to harden lead in making shot, and in certain bronzes. Arsenic compounds, chiefly arsenious oxide or white arsenic, Paris green, $Cu(C_2H_3O_2)_2 \cdot 3CuAs_2O_4$, and lead arsenate are used as insecticides. As_2S_3 or orpiment is used as a pigment. As_2O_3, As_2O_5, As_2S_3, As_2S_5, AsH_3 or arsine, $KAsO_2$, $FeAsO_4$, and $AsCl_3$ are common arsenic compounds. The metal costs about 70¢ per pound ($1.54 per kilogram), whereas the oxide As_2O_3, white arsenic, costs only 6¢ per pound (13¢ per kilogram).

ASTATINE (Gr. *astatos*, unstable). This is the heaviest of the halogens, element No. 85, or Mendeleev's ekaiodine. It was discovered in 1940 by Corson, MacKenzie and Segre who prepared it artificially by bombarding bismuth with high energy alpha particles accelerated in the Berkeley cyclotron. All the known isotopes are short-lived. It is an alpha emitter and has properties similar to polonium. As would be expected, astatine is somewhat less volatile than iodine. Most of the work on this element is done by tracer methods in which the frequency of disintegration is observed.

BARIUM (Gr. *baros*, heavy). Ger. *Barium*. Fr. *barium*. A soft, white metal of the alkaline earth group. It was first isolated by H. Davy in 1808. It never occurs native, but is fairly common as the sulfate, barite, and the carbonate, witherite. Barium is stable in dry air but is readily oxidized by moist air or water at ordinary temperatures. It is malleable and ductile. The element has no important uses but several of its compounds have commercial applications. The carbonate, $BaCO_3$, is used in glass making and is recommended as a poison for destruction of rodents; the sulfate and carbonate are used in the manufacture of paints; $BaCl_2$ is used in purifying salt, in analytical chemistry, and in certain medicinal and photographic preparations; the nitrate and chlorate are used to produce a green color in signal lights and pyrotechny, and for certain explosive mixtures; barium peroxide, BaO_2, is used as a bleach. The porous monoxide is an excellent desiccant. Barium compounds, usually the oxide, are used in emission mixtures in electronic devices such as radio tubes and fluorescent lamps. When heated they emit a stream of electrons which starts the current flowing through the tube. Soluble barium compounds are poisonous. A pound of barium in the form of a chemically pure powder sells for about $30 (7¢ per gram), but the crude sulfate, barytes, costs only about $25 per ton (2½¢ per kilogram).

BERKELIUM (named for Berkeley, California). This is one of the nine trans-uranium elements so far discovered. It was discovered in 1949 by Thompson, Ghiorso, and Seaborg at the University of California in Berkeley. It is the ninth element in the actinide series and, like terbium, its homolog in the lanthanide series, was named for a city important in its discovery. Berkelium was first obtained by bombarding americium with alpha particles from the 60-inch cyclotron.

BERYLLIUM (L. *beryl*). Ger. *Beryllium*. Fr. *béryllium*. Also known as GLUCINIUM (Gr. *glykys*, sweet). Ger. *Glucinium*. Fr. *glycinium*. The symbols are Be and Gl. Beryllium is a dark gray metal lighter than aluminum. It was discovered by L. N. Vauquelin in 1797. Beryllium is a fairly scarce element. It occurs in small amounts in many different minerals but its chief source is beryl, a beryllium aluminum silicate, which is produced only as a by-product in mining other minerals. Only beryl crystals large enough to permit hand-sorting are recoverable since no concentration process is yet economical. The metal is usually produced by the thermal reduction of BeF_2 with magnesium, yielding a solid metal in either lump or massive form. The slag accompanying the metal is removed by washing and vacuum

melting. Another process involves the electrolysis of a fused salt containing $BeCl_2$ and NaCl at a temperature below the melting point of beryllium, thereby producing a flake material. Beryllium presents a serious health hazard. Ingestion of the element or its compounds by breathing or through an open wound may lead to berylliosis, a silicosis-like condition, or carcinoma, for which there are no certain cures. Sensitivity to infection varies greatly among individuals much like an allergy. Beryllium compares favorably with other metals as a structural material on a price per unit volume basis but rather unfavorably with respect to potential supply, and very unfavorably with respect to ductility and workability. However, beryllium is unique among metals as a moderator and it is likely that atomic reactors will make use of this property in spite of its mechanical shortcomings. The metal is used in making light alloys, hard copper, and brass which has remarkable resistance to fatigue. Beryllium was considered an essential metal during the war because of its use as an alloy constituent in springs, cams, gears, precision bearings and contact brushes, and because it was used to produce slow neutrons in the production of the atom bomb. Beryllium salts are usually white and do not color the nonluminous flame. Beryllium salts are used in the manufacture of phosphors in fluorescent lamps, in ceramics and in the manufacture of synthetic gems and incandescent mantles. BeO or beryllia, $BeCl_2$, $BeSO_4$, $BeSiO_4$, $Be(NO_3)_2$, and $Be(AlO_2)_2$ are a few of the most common beryllium salts. A copper alloy having 4% beryllium costs $40 per pound ($88 per kilogram) of contained beryllium. The price of beryllium of fairly high purity in the lump form is about $50 per pound ($110 per kilogram) and purification by vacuum melting adds perhaps another $5 or $10 per pound.

BISMUTH (Ger. *weisse masse*, white mass. Called by miners *wismat;* changed to *bismat* when latinized). Ger. *Wismut.* Fr. *bismuth.* Bismuth is a tin-white metal with a high luster. It is thought to have been known to the ancients who confused it with tin and lead. Its chief source is native bismuth occurring either alone or with tin, gold, silver, etc. It can also be obtained commercially from sulfide or oxide ores. Bismuth is a soft, brittle metal which has the lowest heat conductivity of any metal. Bismuth melts at about 260°C. and its most important use is in the form of low-melting alloys with tin, cadmium, and lead. Some of these alloys melt at 75–80°C. and are used in automatic sprinklers, etc. The electrical resistance of bismuth increases in a magnetic field, which makes it useful in determining the strength of these fields. Certain salts of bismuth such as the salicylate and the subnitrate are used in medicine, while bismuth oxide is used in making an optical glass and an enamel for cast iron. Bi_2O_3, BiOCl, Bi_2O_5, $BiONO_3$, $Bi(NO_3)_3 \cdot 10H_2O$, and $Bi_2(SO_4)_3$ are typical bismuth salts. The metal of about 99.7% purity sells in ton lots for $2.25 per pound ($4.95 per kilogram).

BORON (Ar. or Pers. *borak*, white). Ger. *Bor.* Fr. *bore.* Boron is a black, crystalline powder. It was first prepared in 1808 by J. L. Gay Lussac and L. J. Thenard. It occurs chiefly as borax in which form it is widely used as a cleaning powder. It is one of the less abundant elements in the earth's crust but nature has so concentrated it in a few places that it is a common and inexpensive element. It is essential to plant growth in very small amounts. Boron can be prepared by heating powdered magnesium with boric anhydride until an energetic reaction takes place. The resulting magnesium borate is leached out with water and HCl leaving the boron undissolved. It is seldom made for it has no important commercial uses. Boron is remarkable in that its electrical resistance at room temperature is about two million times its resistance at a red heat. Its most important compounds are borax, $Na_2B_4O_7 \cdot 10H_2O$, and boric acid, H_3BO_3, which is used as an antiseptic and in the plating industry. Borax and boric oxide, B_2O_3, are very important in the ceramic industries. Boric acid and sodium and potassium borates are used as brazing fluxes, while ferro-boron and manganese-boron are used in metallurgy to improve hardenability and to facilitate annealing of certain alloys. The element costs about

a dollar per gram, but borax sells for less than 4¢ per pound (9¢ per kilogram).

BROMINE (Gr. *bromos*, a stench). Ger. *Brom*. Fr. *brome*. Bromine, one of the halogen elements, is a red, caustic, fuming liquid with a very strong, disagreeable odor. It was discovered in 1826 by A. J. Balard. It never occurs in the free state but its compounds are present in sea water and to a greater degree in certain saline springs, especially those of Stassfurt in Germany, and Ohio and Michigan in the United States. It is more abundant than iodine but less so than chlorine or fluorine. Bromine will liberate iodine from its compounds and is in turn liberated from its compounds by chlorine, which is the basis of all technical processes for the production of bromine. Bromine and mercury are the only elements that are liquid at ordinary temperatures. The fumes of bromine are poisonous if inhaled in sufficient volume, and when the liquid is spilled on the skin it produces painful sores. Bromine is used in the preparation of various chemicals, in photography, as a disinfectant, in analytical chemistry, as a bleach, a military gas, and for gold extraction, but its largest use is in the production of ethylene bromide which is added to tetra-ethyl lead when the latter is used as an antiknock in internal combustion engines. The element is usually monovalent, but it exists with valencies of three, five, and seven as well. KBr, NaBr, AgBr, HBr, $CaBr_2$, BrCl, $AgBrO_3$, and $NaBrO_3$ are well known bromine compounds. The wholesale price of bromine is about 27¢ per pound (59¢ per kilogram).

CADMIUM (Gr. *kadmia*, Cadmean (earth) or L. *cadmia*, calamine, a zinc ore). Ger. *Cadmium*. Fr. *cadmium*. Cadmium is a silver-white metal with a bluish tinge. It was discovered in 1817 by F. Stromeyer. It occurs chiefly as greenockite, CdS, which is found with zinc ores, usually in small quantities. The metal is generally obtained as a by-product in the distillation of zinc. The cadmium, being more volatile, distills off in the first fraction. This high cadmium fraction is then redistilled at a lower temperature, yielding cadmium up to 99.5% purity. Cadmium is malleable and ductile, about as hard as magnesium, and melts around 320°C. It is used with bismuth in making low-melting alloys, for making a dental amalgam, as an alloy with silver in electroplating, and as a protective coating on nails, bolts and nuts. Artificially prepared cadmium sulfide and selenide, alone or in combination, are used to produce a variety of paint pigments ranging from lemon yellow to dark red. The sulfide is also used in radar and television phosphors. CdO, CdS, $CdSO_4$, $CdCl_2$, $Cd(NO_3)_2$, and $Cd(OH)_2$ are typical cadmium compounds. The wholesale price of cadmium is about $1.75 per pound ($3.85 per kilogram).

CALCIUM (L. *calx*, *calcis*, lime). Ger. *Calcium*. Fr. *calcium*. A soft, silver-white metal of the alkaline earth group. The metal was first prepared by H. Davy in 1808. None of the alkaline earths occurs free in nature but calcium compounds are very abundant, calcium making up a little more than 3% of the earth's land, sea, and air. Calcium is necessary for human nutrition, about one gram a day being required by the average person. Animal skeletons owe their rigidity mainly to calcium phosphate, and the shells of mollusks and birds' eggs to the carbonate. Calcium is also essential to plant growth. The metal may be prepared by the electrolysis of $CaCl_2$ at a temperature slightly above its melting point. It is used as a reducing agent in the preparation of metals from their oxygen and halogen compounds; as a reagent in the purification of inert gases; as a scavenger and decarbonizer in metallurgy; as a means of fixing atmospheric nitrogen; and for making alloys, especially with aluminum. Calcium compounds are widely used in the manufacture of lime, mortar, bricks, cement, glass, glazes, sugar, paint, paper, and in tanning. Calcium hypochlorite is a common bleaching agent and deodorant, while calcium carbide is used to produce acetylene. CaO, $CaCl_2$, $CaCO_3$, $CaSO_4$, $Ca(NO_3)_2$, and $Ca(OH)_2$ are a few well known calcium salts. The metal costs

about $2.05 per pound ($4.50 per kilogram), but slaked lime, $Ca(OH)_2$, sells for as little as $10 per ton (1¢ per kilogram).

CALIFORNIUM (Named from the State and the University of California). This is the most recently known of the trans-uranium elements. It was first made in 1950 by Thompson, Street, Ghiorso, and Seaborg by bombarding curium with helium ions. Cf-244 is an alpha emitter. Only invisible amounts have been made and its properties have been studied by means of radioactivity tracers. The only state identified is the tri-valent californium which resembles the rare earths.

CARBON (L. *carbo*, coal). Ger. *Kohlenstoff*. Fr. *carbone*. Carbon occurs free in nature and has been known from ancient times. The element exists in two crystalline forms, diamond and graphite, as well as in the amorphous condition as exemplified by lampblack, boneblack, etc. The diamond is the hardest known substance, and has a very high melting point and index of refraction as well. Because of these properties it is much prized as a gem but it is also used to cut glass, drill rocks, and as bearings in watches and other precise instruments. The chief source of diamonds is the blue clay near Johannesburg, South Africa. Graphite occurs as nodules in granite, slate and other rocks but it is sometimes found in large masses. It is gray with a metallic luster and is opaque even in the thinnest flakes. It is very soft and greasy to the touch. Graphite can, like the diamond, be burned to CO_2 at high temperatures. It is used in pencils, as crucibles for melting metals, in electrotyping, for protecting iron from rust, and as a lubricant. It is also used as a moderator slowing down the fast neutrons of the uranium pile in atomic fission. Amorphous carbon, of which there are several kinds, is made by burning various organic substances in an insufficient supply of air. It is soft, black, and slightly more active than graphite, probably because it is in a more finely divided state. Special forms of carbon (activated) are used for their absorptive properties in removing odors, tastes, colors, etc. Carbon is the basic substance around which all organic life revolves. It is found in all plants and animals in the combined state, while great deposits of coal are known which consist mainly of carbon either free or combined. The carbon dioxide present in the air is the sole source of carbon in plant life. The number of known carbon compounds is around a quarter of a million, while the number of possible compounds is almost unlimited. $CaCO_3$, CO_2, CO, CS_2, CCl_4, $CHCl_3$, C_2H_5OH, CH_3COOH, $(COOH)_2$, and $C_2H_5OC_2H_5$ are a few of the most important carbon compounds. The wholesale price of graphite is from 21¢ to 29¢ per pound (46¢ to 64¢ per kilogram), while carbon black runs from 6¢ to 12¢ per pound (13¢ to 26¢ per kilogram).

CERIUM (Named from the asteroid, *Ceres*, which was discovered three years before the element). Ger. *Cerium*. Fr. *cérium*. A steel-like appearing metal of the rare earth group, which is malleable and ductile and can be cut with a knife. It was discovered by Berzelius and Hisinger in 1804. Cerium, the most abundant of the rare earths, is usually found in monazite sand, cerite, gadolinite and samarskite. The metal can be prepared by the electrolysis of the chloride. Cerium is separated from mixtures with the other rare earths by oxidation to the ceric state and subsequent removal. Iron-cerium alloys are pyrophoric and are used in automatic lighters. An alloy of cerium with lanthanum and the other rare earths, known as *mischmetall*, is a valuable reducing agent. The use of cerium in steels prevents crystallization, while alloys of cerium with aluminum or magnesium are tough light and heat-resistant. Gas mantles contain about one percent CeO_2; cerium salts, especially the fluoride are introduced into arc-lamp electrodes which makes them burn more brightly, quietly, and evenly. Ceria is used to make glass of good heat protecting properties. Cerous salts (valence 3) are colorless; ceric salts (valence 4) are yellow, orange or red. Cerium is used in certain photo-

electric cells. Ceric oxalate is used in medicine, and the sulfate is being used in titrimetric analysis in place of $KMnO_4$ or $K_2Cr_2O_7$, it having the advantage of yielding colorless reaction products. Ce_2O_3 or ceria, CeO_2, $Ce_2(CO_3)_3$, and $CeCl_3$ are a few of the better known cerium compounds. A technical grade of the element costs $36 per pound ($79 per kilogram) but some of its compounds are relatively cheap; a 77% grade of CeO_2 sells for $1.74 per pound ($3.83 per kilogram).

CESIUM (L. *coesius*, sky-blue). Ger. *Cäsium*. Fr. *césium*. Cesium is a silvery white alkali metal resembling rubidium and potassium. It was discovered with the aid of the spectroscope in 1860 by Bunsen and Kirchhoff. Cesium is the heaviest of the known members of the alkali series of metals, and is the most electropositive of all metals. It is the softest of all solid metals, being softer than beeswax, and must be kept out of contact with air or water. Its chief source is the mother liquors from the production of KCl from carnallite. Cesium is never found in large quantities. It is used in certain photoelectric cells, and in vacuum tubes to remove traces of gases. Cesium compounds color the nonluminous flame violet. CsOH, CsCl, CsCN, and $CsHC_4H_4O_6$, the acid tartrate, are some common cesium salts. The price is about $14 a gram.

CHLORINE (Gr. *chloros*, grass green). Ger. *Chlor*. Fr. *chlore*. Chlorine is a greenish-yellow gas with a disagreeable odor. It was produced by Scheele in 1774 but its elemental nature was first proved by Davy in 1808. Chlorine, the most abundant of the halogens, does not occur free in nature but chlorides and other chlorine-containing compounds are very common. Sodium chloride is the most important source for both chlorine and sodium, it being found in huge deposits as well as being present in sea water and in most brines. Chlorine is generally made by the electrolysis of sodium chloride, it being a secondary product in the manufacture of sodium hydroxide. Chlorine is non-combustible but it will support the combustion of certain compounds. A candle will burn in chlorine with a smoky flame, the hydrogen in the paraffin combining with the chlorine while the carbon is liberated. Chlorine is used as a bleaching agent, a water disinfectant, a war gas, and as an intermediate in the preparation of other compounds, one of the most important of which is calcium hypochlorite or bleaching powder. Sodium chloride is a necessary constituent of animal diets. Chlorine can act with a valence of 1, 3, 4, 5, and 7 as illustrated by the compounds NaCl, $KClO_2$, ClO_2, $KClO_3$, and $KClO_4$. Hydrochloric acid, HCl is one of the three common mineral acids. In tank car quantities the price of chlorine is a little under 3¢ per pound; in 150 pound cylinders the price is 9½¢ per pound (21¢ per kilogram).

CHROMIUM (Gr. *chroma*, color). Ger. *Chrom*. Fr. *chrome*. A hard, bright, silvery metal capable of taking a high polish. It was discovered in 1797 by L. N. Vauquelin, whose work was confirmed by M. H. Klaproth. The principal ore of chromium is chromite, $FeO \cdot Cr_2O_3$. Most of the chromium comes from New Caledonia, the United States, India, and Canada. The metal is generally prepared by the reduction of Cr_2O_3 with silicon, hydrogen or some other reducing agent, the chromic oxide being made from chromite by heating the refined ore with an alkali, acidifying to form the alkali dichromate, and reducing this to the insoluble Cr_2O_3 and a soluble alkali salt, the latter being leached out with water. The metal which has been electrically deposited has a hardness of 9 on the scale where diamond is 10 and is much harder than metal prepared in other ways. Objects electroplated with chromium have a beautiful silvery finish that is very resistant to all kinds of corrosion. There are many important chromium alloys such as steel with about two percent chromium, as well as various nickel-chromium and chrom-vanadium steels. The addition of chromium to an alloy generally adds to its toughness, hardness, strength and resistance to corrosion. Perhaps the largest use of chromium is in the form of chromite as

a refractory lining in open-hearth and other furnaces. Chromium compounds are highly colored and are much used as pigments. They are also used in tanning, in making safety matches, as antiseptics, as components in certain galvanic cells, and for many other purposes. K_2CrO_4, $Cr(OH)_3$, Cr_2O_3, CrO_3, and $PbCrO_4$ are typical chromium compounds. The price is about $1.20 per pound ($2.64 per kilogram).

COBALT (Gr. *kobolos*, a goblin). Ger. *Kobalt*. Fr. *cobalt*. Cobalt is a bright silvery metal and is a member of the iron-cobalt-nickel triad. It was first prepared by Georg Brandt in 1735; cobalt compounds, however, were first studied by Thenard in 1802. It is not very widely distributed; among the more important ores are cobaltite (CoAsS), smaltite ($CoAs_2$), erythrite ($Co_3(AsO_4)_2 \cdot 8H_2O$), and wad ($Co_3S_4$). The most important deposit of cobalt ores is the one at Cobalt, Ontario, where the cobalt arsenide is mixed with nickel and silver. These ores are ground, smelted, roasted, and washed in a series of steps that result in the recovery of nickel and cobalt oxides, silver, and arsenious oxide. The Co_3O_4 which is the form usually sent to the refinery is reduced to the metal with carbon, hydrogen or aluminum. Cobalt is not quite as magnetic as iron but is harder than iron or nickel; like iron, its hardness and tensile strength are much improved by the addition of small amounts of carbon, usually to the extent of 0.25% or less. Too much carbon makes cobalt brittle. Unlike iron, cobalt is not attacked by air and water at ordinary temperatures but it is superficially oxidized at a red heat. Cobalt may be electroplated, depositing a coating with properties superior to that obtained by nickel plating. Many valuable cobalt alloys are known such as stellite and cochrome, the latter being the same as nichrome with the nickel replaced by cobalt. This alloy, which is used for electrical heating units, melts at a higher temperature and is more resistant to corrosion than the corresponding nickel alloy. Combined with nickel and aluminum, cobalt is used in making the very powerful Alnico magnets. A cobalt amalgam is used in dentistry. Certain cobalt salts are used to impart a beautiful blue color to glass, pottery, enamels and paints. Several organic cobalt salts such as the oleate, acetate, linoleate, etc. are used as dryers in the paint and varnish industry. Cobalt forms divalent and trivalent compounds but the latter are generally unstable except in the double salts. $CoCl_2$, $Co(ClO_3)_2$, $Co(OH)_2$, Co_3O_4 or cobalto-cobaltic oxide, $CoSO_4$, and $Co(NO_3)_2$ are common cobalt salts. The price of cobalt of 97–99% purity is about $2.60 per pound ($5.72 per kilogram).

COLUMBIUM, see *Niobium*.

COPPER (L. *cuprum*, copper). Ger. *Kupfer*. Fr. *cuivre*. Copper is a reddish-brown, ductile metal. It is found native in large masses and has been known from the earliest times. The metal is also obtained from ores such as covellite (CuS), tenorite (CuO), cuprite (Cu_2O), chalcocite (Cu_2S) and azurite ($Cu_3(OH)_2(CO_3)_2$). Copper ores are found in many countries but the United States is the largest producer. The metal is usually prepared by roasting and smelting the ore and then making the final purification by electrolysis. Copper is one of the best conductors of heat and electricity, and consequently is widely used in making boilers, steam pipes, cooking utensils, chemical apparatus, and wires for telephones and telegraphs as well as for the distribution of current. Copper rollers are used in calico printing. Its alloys are very important, including brass, bronze, gun-metal, German silver and many others. All United States coins contain from 10% to 95% copper. Copper salts are used in medicine, for combating pests, and as antiseptics. CuO, Cu_2O, $CuSO_4 \cdot 5H_2O$, CuOH, CuCl, and $Cu(NO_3)_2$ are well known copper salts. In large quantities the price of copper is about 40¢ per pound (88¢ per kilogram).

CURIUM (Named for the Curies, discoverers of radium). This trans-uranium

element, No. 96, was named after a person as was its homologue, gadolinium. Curium was discovered in 1944 by Seaborg, James, Morgan, aud Ghiorso in connection with their work on the atom bomb project at the University of California. It was the third of the transuranium elements to be discovered and was produced by the irradiation of Pu-239 with helium ions in a cyclotron. It can also be made from americium by neutron bombardment. One of its isotopes, Cm-242, is an alpha emitter. Because of its very high rate of alpha emission, 7 billion alpha particles per minute per microgram going from Cm-242 to Pu-238, all work with curium must be carried on behind adequate shielding. So far it is known only in the trivalent state.

DYSPROSIUM (Gr. *dysprositos*, hard to get at). Ger. *Dysprosium*. Fr. *dysprosium*. Dysprosium is a rare earth metal of the yttrium group and has not yet been described. It was discovered in 1886 by Lecoq de Boisbaudran. The compounds of dysprosium are found in very small quantities in the minerals blomstrandine, euxenite, fergusonite, gadolinite, and polycrase, together with the other rare earths. It is widely distributed in the earth's crust. Dysprosium salts are yellow or greenish-yellow in color. Dy_2O_3 or dysprosia, $DyCl_2$, $Dy_2(SO_4)_3$, $Dy(NO_3)_3 \cdot 6H_2O$, $Dy_2(CO_3)_3 \cdot 4H_2O$ and a few others have been described. They have no commercial application.

ERBIUM (*Ytterby*, a town in Sweden). Ger. *Erbium*. Fr. *erbium*. Erbium has been isolated as a dark gray metallic powder which was probably impure. It was discovered in 1843 by C. G. Mosander. Erbium occurs with other rare earths in minerals such as gadolinite, blomstrandine, euxenite and a few others. Its compounds are pink or rose colored and have a sweet, astringent taste. A few compounds of erbium including Er_2O_3 or erbia, $Er_2(SO_4)_3$, $Er(NO_3)_3 \cdot 5H_2O$ and others have been prepared. They are not used commercially.

EUROPIUM (*Europe*). Ger. *Europium*. Fr. *europium*. Europium is one of the least abundant of the rare earth elements. The metal has not yet been prepared, and few of its salts are known. Europia (Eu_2O_3) was isolated in 1900 by Demarcay, and prepared in a state of purity by Urbain and Lacombe in 1904. Europium compounds are pale pink in color. $EuCl_3$, $EuCl_2$, Eu_2O_3, $Eu_2(SO_4)_3$ and a few organic salts have been prepared and described.

FLUORINE (L. *fluere*, to flow). Ger. *Fluor*. Fr. *fluor*. Fluorine is a pale, greenish-yellow gas of the halogen family and is very pungent and corrosive. The gas was isolated in 1886 by H. Moissan after a period of more than 75 years of effort on the part of many experimenters. Fluorine is the most chemically active of the elements. It occurs in the combined form in fairly large quantities being second only to chlorine in abundance among the halogens. The moist gas will attack glass but dry fluorine is without action. It is prepared by electrolyzing a solution of potassium fluoride in liquid HF or molten KHF_2. The chief ores of fluorine are fluorspar (CaF_2), and cryolite (Na_3AlF_6). Fluorine will combine with all elements except the inert gases. It is so active that solid fluorine and liquid hydrogen explode when brought together at −252°C. The free element is difficult to prepare and is seldom used except in research work. An important war use of fluorine was to prepare uranium hexafluoride for use in the atom bomb project. Fluorine gas is used to make SF_6, an insulating gas used in high voltage X-ray machines, and also to make Cl_3F, a material nearly as active as fluorine itself but which, unlike fluorine, can be shipped in liquid form in cylinders. Cryolite is an essential material in the production of aluminum and is used, as is sodium ferric fluoride, as a "getter" in incandescent lamp manufacture. Hydrogen fluoride

is used for etching glass; in the fermentation industries for checking the growth of wild yeasts; to coagulate rubber latex; in the laboratory for analytical purposes, especially the estimation of silica; and for opening boring holes in gas and petroleum wells, the acid being used to dissolve the siliceous material. A plastic with excellent chemical inertness is made by polymerizing tetrafluoroethylene. Soluble fluorides are poisonous; NaF, for example, being a common insecticide. Boron fluoride is used as a catalyst. Traces of fluorides in the water supply are believed to prevent tooth decay in children but small amounts greater than traces cause a detrimental effect known as "mottled teeth." A few typical fluorine compounds are NaF, CaF_2, KF, AgF, and AlF_3. Generators can be purchased in which the gas can be produced for from 50¢ to $2.00 per pound ($1.10 to $4.40 per kilogram) depending on the quantity made. Fluorine is now available in cylinders.

FRANCIUM (Named for France, the native country of its discoverer). This is element No. 87, the heaviest of the alkali metals. It was discovered in 1939 by Marguerite Perey at the Curie Institute, Paris. Francium, formerly called *actinium K* by Mlle. Perey, occurs as an alpha disintegration product of actinium. This particular isotope is a beta-emitter. Since francium is only a minor product of actinium decomposition, there probably exists only a little over 20 grams of naturally occurring francium in the earth's crust to a depth of one mile.

GADOLINIUM (Named for J. Gadolin, the Finnish chemist). Ger. *Gadolinium*. Fr. *gadolinium*. The element has not been prepared, but several of its salts are known. Gadolinium was discovered in 1886 by Marignac. It is generally found with other rare earths, especially those of the terbium family, of which it is a member. The gadolinium ion is colorless. Among the salts of this element which have been prepared are Gd_2O_3 or gadolinia $GdCl_3$, GdF_3, Gd_2S_3, $Gd_2(SO_4)_3$, $Gd(NO_3)_3 \cdot 6H_2O$, and several organic salts.

GALLIUM (L. *Gallia*, France). Ger. *Gallium*. Fr. *gallium*. Gallium is a steel-gray metal. It was discovered in 1875 by L. de Boisbaudran. The element is widely distributed but the total amount in the earth's crust is very small. It is obtained from certain zinc blendes in which it occurs as a very slight impurity. Gallium is unique in that it melts at 30°C. and yet is not very volatile at a red heat. These properties make the metal valuable for use in thermometers for high temperatures. It is also capable of being greatly supercooled; and, when solid, is much harder than other low-melting metals. Like water, it expands upon solidification. It has a very limited use in dental alloys, as an activator in phosphors and luminous paints, and as a liquid seal in the inlet systems of mass spectrometers. Gallium has a valence of three, and forms salts resembling those of aluminum, such as $GaCl_3$, Ga_2O_3, Ga_2S_3, and $Ga_2(SO_4)_3$. It also forms divalent salts such as $GaCl_2$, etc. The price is about $1000 per pound ($2.20 per gram).

GERMANIUM (L. *Germania*, Germany). Ger. *Germanium*. Fr. *germanium*. Germanium is a grayish-white metal of the silicon family, appearing in the periodic table between silicon and tin. It was discovered in 1886 by C. Winkler, but it had been predicted before this by Mendeleev, who called it eka-silicon. The element is rather scarce and is found in small quantities in the ores of silver, copper, zinc, and a few other metals. It can be separated from most of its associates by precipitation from acid solution with H_2S. The metal may be prepared by reducing the sulfide with hydrogen or carbon. Germanium compounds are plant stimulants in very low concentrations, toxic in higher. Germanium is used to make transistors, tiny devices which can replace vacuum tubes in many of their applications of rectification and amplification of electric current. For this use the element is more easily

purified than is silicon and it has excellent properties up to about 100°C. Silicon transistors, however, can operate up to about 200°C. Germanium resembles silicon in forming a gaseous hydride GeH_4, while K_2GeF_6 is like K_2SiF_6. GeO_2, GeS_2, GeO, GeS are typical compounds. The price is about $295 per pound (65¢ per gram).

GOLD (Anglo-Saxon, *gold*. Sanskrit, *juel*, to shine). Ger. *Gold*. Fr. *aurum*. Like most metals that are found in the free state, gold has been known from ancient times. It is bright yellow in color, is very soft and heavy, is the most malleable and ductile of all metals, is a good conductor of heat and electricity, and is not acted upon by air, water, or most reagents. The metal is generally found native in rocky or sandy deposits. After concentrating the ores, the gold is extracted by the amalgamation process or the cyanide method. It is widely used in coinage, being the standard for monetary value in most countries. The metal is generally alloyed with copper or silver to make it hard enough to stand wear; such alloys are used in jewelry and other ornaments. Gold forms compounds in which it is either tri- or mono-valent. Gilding is often accomplished electrolytically, usually with sodium gold cyanide or chloroauric acid, $HAuCl_4$. Many gold compounds are used in medicine, and several, notably $AuCl_3$, are of use in photography. The United States Government sets the price of gold at $510.42 per pound avoirdupois.

HAFNIUM (L. *Hafnia*, Copenhagen). Ger. *Hafnium*. Fr. *hafnium*. Hafnium is a metal resembling zirconium, and is found in nearly all ores of that metal. It was discovered in 1922 by D. Coster and G. Hevesy. The average hafnium content of all zirconium ores is about three percent of the amount of zirconium in the ore, but the minerals alvite, cyrtolite, and thortveitite are much richer than this in hafnium. This element is number 72 in the periodic table. Urbain thought he had discovered number 72 in Marignac's ytterbium and named his new element "celtium," but this is now believed to have been a concentrated sample of lutecium. It is very difficult to separate hafnium from zirconium. This is generally accomplished by many fractional crystallizations of the mixed potassium hexafluorides, K_2HfF_6 and K_2ZrF_6. The metal is prepared by reducing K_2HfF_6 with sodium. Hafnium, with its high neutron cross section, is useful for reactor controls.

HELIUM (Gr. *helios*, the sun). Ger. *Helium*. Fr. *hélium*. Helium is a very light, colorless, odorless, inert, atmospheric gas. It was found spectroscopically in the atmosphere of the sun by Lockyear in 1868. The gas was first isolated by Ramsay in 1895. Helium is present to a very slight degree in air, and to a much larger extent in certain mine gases and dissolved in spring water. Helium is a disintegration product of radioactive substances, so it is generally found in the ores of uranium, radium, etc. and from which it may be obtained by heating the mineral and pumping off the resulting gases. The chief source of helium is certain gas wells in the Texas-Panhandle containing 1 to 2% of the element; a more recently discovered supply has been found in wells of southeastern Colorado yielding as high as 7%, while a field in northwestern New Mexico produces gas with an 8% helium content. The best known foreign source, the blue rock salt of Germany, yields gas with only 0.001% to 0.19% helium. It is an extremely rare element in the crust of the earth where it is present in an occluded state or trapped in tiny holes in the rocks. The chief use of helium is to inflate lighter-than-air machines; although heavier than hydrogen its advantage is due to the fact that it will neither burn nor support combustion. It has been used for the production of the lowest temperatures ever obtained; i.e., below −271°C. The most important use of helium is to replace the nitrogen in the air in caissons and for administration in asthmatic conditions. For the former it is less soluble in blood than is nitrogen; for the latter it is lighter and more penetrative in the narrowed passages permitting easier

breathing. When multiple optical lenses are arranged in series, helium may be used to fill the spaces between them as light rays passing from a lens to helium are refracted less than in any other gas. Because of the ease of its detection it has been used as a tracer gas and allowed to diffuse through reservoir formations. Helium has been used to reduce the hazards of welding magnesium and as a diluent for anesthetic gases where its rapid diffusion aids in lung penetration and subsequent clearing of the anesthetic, and its inertness serves to prevent explosion of flammable anesthetic gas. A cylinder holding 146 cubic feet (4134 liters) at atmospheric pressure can be filled for $18.55.

HOLMIUM (From *Holmia*, latinized form of Stockholm, near which the rare earth minerals are found). Ger. *Holmium*. Fr. *holmium*. Holmium is one of the least abundant of the rare earth metals. It has never been isolated, the oxide holmia, Ho_2O_3, being very difficult to obtain in a pure state. The element was discovered in 1879 by P. T. Cleve. Holmium salts, a few of which have been prepared, are yellow with an orange tinge.

HYDROGEN (Gr. *hydro genes*, water former) Ger. *Wasserstoff*. Fr. *hydrogène*. Hydrogen is a colorless, odorless, combustible gas. Although it was known to the alchemists, hydrogen was first recognized as a distinct substance by Cavendish in 1766. Hydrogen occurs in the free state in certain natural gases and in volcanic exhalations. Hydrogen is one of the major components of the earth's atmosphere above 13 miles. In water one part of hydrogen is combined with eight parts of oxygen and from which it can be separated by electrolysis, the usual method of preparing the pure gas. It is also obtained by the action of acids on metals and by the action of steam on certain metals such as iron at a red heat. Hydrogen is element number one in the periodic table; it has the lowest atomic weight of any element and is the lightest gas; the hydrogen molecule diffuses faster than any other. The gas is used in the oxy-hydrogen flame in welding, in hydrogenating oils, fats and other substances, for filling balloons, and as a reducing agent. Hydrogen is a necessary constituent in hundreds of important compounds. All acids owe their acidity to the presence of the hydrogen ion in their solutions. All hydrocarbons, carbohydrates, proteins, fats, in fact nearly all organic compounds contain hydrogen. A cylinder holding 176 cubic feet (4984 liters) at atmospheric pressure can be refilled for about five dollars.

DEUTERIUM (Symbol D) is the isotope of hydrogen with an atomic weight of two. It was discovered in 1931 by H. C. Urey with the aid of F. G. Brickwedde and G. M. Murphy in distilling liquid hydrogen near its triple point of 13.92° *K*. Normally hydrogen contains about one part deuterium in 5,000. Most deuterium is produced by an electrolytic process as a compound with oxygen; namely, as heavy water or D_2O. In atomic energy research heavy water became important because of its action as a moderator. Plants and animals cannot live in water containing a high percentage of D_2O. The use of deuterium makes possible the tracing of food in metabolic processes. Incorporating small amounts in an animal's food and later locating the deuterium in the various tissues or excretory products is the method employed in this work. A very pure deuterium in glass at normal pressure sells for about $10 a liter. The isotope of atomic weight three is much less abundant than deuterium. It is called **TRITIUM.**

INDIUM (From its indigo-blue spectrum line). Ger. *Indium*. Fr. *indium*. A metal of the aluminum family, it is silvery white, very malleable and ductile, softer than lead, unaffected by air or water but on ignition forms In_2O_3. It was first isolated in 1863 by F. Reich and T. Richter. Indium is a rare metal and never occurs native but is found as impurity to the extent of about 0.1% in various zinc ores. As an alloying material with non-ferrous metals it increases cor-

rosion resistance and decreases the melting point. An alloy of indium, cadmium, bismuth, lead and tin melts below 50°C. and is used to make casts for broken limbs. The metal is used to coat chemical pumps and to replace chromium in bright work. Indium and its compounds are used in jewelry, pharmaceuticals, soldering fluxes, electrical contacts, dental alloys, glass colorants, and mordants. Greater production and increased uses in recent years have lowered the price materially. The price is about $32 per pound ($70 per kilogram).

IODINE (Gr. *iodes*, violet). Ger. *Jod.* Fr. *iode.* The German symbol of J for iodine, and the French symbol of Az for nitrogen are the only instances of different national usage in this respect. Iodine, one of the halogen elements, is a bluish-black, crystalline solid which is converted into a violet vapor on heating. It was discovered in 1811 by B. Courtois. Gay Lussac aided him in investigating the new substance and in proving it to be an element. Iodine does not occur free in nature but its compounds are found in sea water as well as in sea plants and animals. Certain varieties of kelp absorb it from the water in preference to bromine which occurs in much larger quantities. In the earth's rocky crust, iodine must be classed as a rare element. Iodine was formerly obtained from the ashes of seaweeds, but most of it is now made from the mother liquors after the extraction of sodium nitrate from the caliche of Chile in which iodine is present in the form of iodates. The iodine is obtained from iodates by heating them with sodium bisulfite. Iodine plays an important part in animal economy, it being present in small quantities in all the organs, especially the thyroid gland. The element is used in medicine, both as a tincture (the free element dissolved in alcohol) and in compounds, mostly for external use as antiseptics. Iodine is important in analytical chemistry as are several of its compounds, notably KI and KIO_3. Some iodides are used in photography. A considerable amount of iodine is used in the aniline dye industry. It acts as a powerful poison. Iodine usually has a valence of one, forming iodides such as NaI, KI, AgI, BiI_3, CaI_2, etc. It also forms iodates (salts of iodic acid, HIO_3) and periodates (salts of periodic acid, HIO_4). Trivalent iodine is known in compounds like ICl_3. The wholesale price of crude iodine is about $1.30 per pound ($2.80 per kilogram).

IRIDIUM (So named from the iridescent color of its salts). Ger. *Iridium.* Fr. *iridium.* Iridium is a metal of the platinum family. It is hard, brittle, nonductile, and in appearance lies between silver and tin. Iridium was first identified as a new metal by Tennant in 1804. It is found in alluvial deposits alloyed with platinum as platiniridium, or with osmium as osmiridium. The metal is generally obtained by precipitation from solution as $(NH_4)_2IrCl_6$; this is then heated in a current of hydrogen, leaving the impure iridium which must further undergo a complicated process to remove traces of rhodium, ruthenium and iron. Iridium, when alloyed with platinum, forms a hard, resistant metal that is used to make scientific apparatus, surgical tools, standard weights and lengths, and pen points. Because of its hardness the element itself is used to make pivots and magneto contacts. Iridium black, made by the action of light on alcoholic sulfate solutions, is used as a catalytic agent. Acids, even aqua regia, do not act on iridium, while fluorine and chlorine do not act until a red heat is reached. Fusion with KOH and KNO_3 results in the formation of K_2IrO_4. $IrCl_4$, $IrCl_3$, $K_3IrCl_6{\cdot}3H_2O$, Ir_2O_3, IrO_2, and $KIr(CN)_6$ are some typical iridium compounds. The wholesale price of the metal is about $179 per troy ounce ($5.47 per gram).

IRON (Anglo Saxon, *iren*, or *isern.* Latin, *ferrum*, from which is derived the symbol Fe). Ger. *Eisen.* Fr. *fer.* Iron is a bright, silvery white metal which tarnishes in air or water. Perfectly dry air does not affect it, but under normal atmospheric conditions an unprotected sample will, in time, rust away completely. Next to aluminum, iron is the most abundant of all metals, and has been known from very early times. It is

sometimes found native in meteors, in which it is alloyed with from 1 to 10% of nickel. The usual source of the metal is magnetite (Fe_3O_4) and hematite (Fe_2O_3), which are the ores that are mined in vast quantities in the Lake Superior district. The iron is obtained by reducing the ores with carbon in a blast furnace. The fusible carbide, cast iron, can be purified by "puddling" in a reverberatory furnace with ore, limestone, etc., to remove C, S, P and Si with mechanical working to produce wrought iron; or completely fused at a higher temperature for steel, to which alloying additions may be made. Pure iron is rather soft, malleable and ductile. Small amounts of carbon greatly change these properties, making the iron harder and of higher tensile strength; too much carbon makes iron brittle. Iron is very strongly magnetic. It is readily attacked by dilute mineral acids, but can be rendered passive by concentrated nitric acid. Pure iron is seldom used except in medicine for treatment of anemia, and in analytical work as a reducing agent, but the so-called "ingot iron" and electrolytic iron are nearly pure, as are certain low carbon steels. The quality of steel is greatly improved by the addition of small amounts of nickel, cobalt, chromium, vanadium, or tungsten. FeO, Fe_2O_3, $FeSO_4$, FeS, $FeCl_3$ and $Fe(NO_3)_3$ are typical iron compounds. Crude pig iron sells for about $51 per ton ($57 per metric ton) but U. S. P. powdered iron costs about $1.10 per pound ($2.42 per kilogram).

KRYPTON (Gr. *kryptos*, hidden). Ger. *Krypton*. Fr. *crypton*. Krypton is one of the rare, inert atmospheric gases. It was first isolated by W. Ramsay and M. W. Travers in 1898 by fractionally distilling liquid argon which contained the other inert gases and among which krypton is present to the extent of about 0.01% of the crude argon. It is seldom used in the pure state but is usually allowed to remain in the argon which is used in filling light bulbs. Because of its greater heat conductivity pure krypton is used in place of argon in mine safety lamps. In glass at normal atmospheric pressure, a liter of pure krypton sells for about $30 ($850 per cubic foot).

LANTHANUM (Gr. *lanthano*, to be concealed). Ger. *Lanthan*. Fr. *lanthane*. Lanthanum, a tin-white metal which is malleable but not ductile, was discovered in 1839 by C. G. Mosander. It burns in air at 440–460°C. to form the oxide La_2O_3, and generally occurs with the other rare earth elements in the combined form in such minerals as scheelite, monazite, apatite, cerite, orthite, as well as in certain kinds of calcite and fluorspar. The element is fairly common. Lanthanum salts are colorless unless derived from a colored acid. Most of the usual salts of lanthanum have been prepared, such as the chloride, $LaCl_3$, from which the metal is made by reduction with sodium, the sulfate, $La_2(SO_4)_3$, etc. La_2O_3 is the strongest base of all the rare earth oxides. It is used in making optical glass of high refractive index. The price of the metal is about $9 per gram.

LEAD (Medieval *led*, *leed*, *lead*. Anglo-Saxon *léad*, akin to Danish *lood*. L. *plumbum*, from which we get the symbol Pb). Ger. *blei*. Fr. *plomb*. Lead is a dull, gray, heavy metal with little tenacity. It is very soft and easily fused, and has been known from ancient times. Lead is seldom found native, its most common ore being galena (PbS). Cerussite ($PbCO_3$), and anglesite ($PbSO_4$) occur in sufficient quantities to be mined, and a rare mineral plumbojarosite is used as an ore in Utah. The ores are roasted in some cases to form the sulfate, sulfide and oxide in such proportions that when the temperature is raised they react to form lead and sulfur dioxide. In the iron reduction process the ore is heated with iron, and the lead is set free. It is used in making pipes, sulfuric acid chambers, and other containers for corrosive liquids. Vast quantities are used in the lead plate type of storage battery, as well as in many valuable alloys such as Babbitt and type metal, shot, solder and pewter. Lead compounds are very important in the paint industry, white lead ($2PbCO_3 \cdot Pb(OH)_2$), red lead (Pb_3O_4), and lead chromates such as $PbCrO_4$ being common pigments while lead linoleate and other lead salts of fatty acids are well-known paint driers. Lead compounds are used in the manufacture of flint glass and enamels;

lead oxide is used in vulcanizing rubber; the ethide, $Pb(C_2H_5)_4$ is a popular gasoline antiknock; and sodium plumbite (Na_2PbO_2) is used to sweeten gasoline by removing the sulfides as PbS. Lead is the stable end product of all natural radioactive elements. Radium D is one of the radioactive isotopes of lead. The nature of these isotopes as shown by the molecular weight of the lead found in a certain region is taken as an indication of its geological age. Lead and its soluble compounds are cumulative poisons, repeated small doses being as dangerous as a single large dose. Exposure to dust containing lead is a common cause of poisoning, "painters' colic" being an example. PbO, PbO_2, $Pb(NO_3)_2$, $Pb(C_2H_3O_2)_2$, and K_2PbO_3 are typical lead compounds. The wholesale price is about 13½¢ per pound (30¢ per kilogram).

LITHIUM (Gr. *lithos*, stony). Ger. *Lithium*. Fr. *lithium*. Lithium, first in the alkali group of metals, is silvery white in color but it must be preserved in a well-stoppered bottle under a liquid which contains as little oxygen as possible to prevent tarnishing. Lithia, Li_2O, was discovered in 1817 by A. Arvedson in petalite. H. Davy, somewhat later, succeeded in isolating a little of the element by electrolyzing LiCl. The element, never occurring free, is widely distributed in its compounds and is slightly less abundant than copper in the earth's crust. The principal sources in the United States include Searles Lake in California, the Black Hills in South Dakota and the Kings Mountain District of North Carolina. In Canada workable deposits occur in the Lacorne area of northwestern Quebec and the Cat Lake area of Manitoba. A large deposit of high-grade ore in Rhodesia is being developed. It is the lightest of all metals, has the highest specific heat of any element, and is the hardest of the alkali metals being about as hard as lead. The first major application of lithium came in the 1880's when it was used in the Edison batteries which are still widely used in railway signal systems, electric trucks, mine locomotives and other heavy duty equipment where dependability is required. It is used as a degasifier, deoxidizer and desulfurizer for molten metals, as a hardener in lead base alloys, and as a grain refiner of nonferrous metals. Thus used as a refining agent, lithium is enclosed in aluminum, bronze or other metal and added to molten metal of the same type. The carbonate and the citrate are used in medicine, the carbonate in ceramic glazes, the chloride in air conditioning, the fluoride as a flux in welding aluminum, and the hydride in generating hydrogen. In the form of compounds such as the zirconate, cobaltite, or manganite, the element is used in porcelain enamels to give greater adherence, improved thermal shock, lowered firing temperatures, improved acid resistance, and increased opacity. The stearate is put in lubricating greases to speed flow in sub-zero cold. The emphasis on lithium-based greases makes it appear likely that within a few years all automotive greases will contain such compounds. The element is likely to command a leading position in the atomic energy field due to its adaptability to both fissionable and fusionable reactions, involving a higher power factor and greater degree of utilization than the much better known uranium. It is thought by some that lithium may in time replace uranium as the prime source of fuel for nuclear energy. This has spurred a world-wide hunt for new sources of supply. U. S. lithium production in terms of lithium carbonate has increased from 645,000 pounds in 1947 to 4 million in 1952. Output at present is near a 10-million pound annual rate and should keep climbing rapidly for many years to come. For fissionable reactions the ordinary form of lithium (lithium-7) when joined by a proton splits into two helium nuclei. On an equal weight basis, the energy thus released is almost three times greater than that from uranium-235. In fusion reactions, lithium-6 combines with tritium (hydrogen-3) to give two helium nuclei and a free neutron. Tritium, which is extremely rare in nature, can be produced by bombarding lithium-6 with neutrons in a uranium pile, the resultant reaction yielding tritium and helium. If lithium turns out to be a feasible and practical source of nuclear fuel it will have certain advantages over uranium and thorium since it is more plentiful and easier to extract, there would be no

radioactive by-products which are one of uranium's chief hazards, and it would be cheaper and yet yield three times greater energy than the same amount of uranium. The price of lithium is about $11.00 per pound ($24.20 per kilogram) but lithium chloride costs only about $1.25 per pound ($2.75 per kilogram).

LUTETIUM (From *Lutecia*, ancient name of Paris). Ger. *Lutetium*. Fr. *lutétium*. Lutetium is the last of the rare earth elements in the periodic table. It was discovered in 1905 by G. Urbain and is found in various rare earth minerals, especially those containing yttrium. Lutetium is one of the less abundant of the rare earths. The metal has not been prepared in the pure state, but a few salts are known, including lutetia, Lu_2O_3, and the sulfate, $Lu_2(SO_4)_3$.

MAGNESIUM (L. *Magnesia*, a district in Asia Minor). Ger. *Magnesium*. Fr. *magnésium*. Magnesium is a very light, silvery white metal that tarnishes slightly in air. In 1808 H. Davy proved that magnesia was the oxide of a metal which he called magnium. This name was later changed to magnesium. The metal was isolated by Bussy in 1829. It does not occur free in nature, but its compounds are quite common. Magnesite ($MgCO_3$), dolomite ($MgCO_3 \cdot CaCO_3$), carnalite ($KCl \cdot MgCl_2$), and Epsom salt ($MgSO_4 \cdot 7H_2O$) are common magnesium minerals. The metal is generally made by electrolyzing the fused chloride. In this country the chief sources of magnesium are the Michigan brines and sea water. Magnesium as a powder or a ribbon will burn in air with a brilliant, white flame, and in these forms is used as a "flashlight powder" and for pyrotechnics. It is the easiest of all metals to machine, and can also be cast, rolled, or forged. An alloy of about 90% magnesium and 10% aluminum is widely used because of its high strength per pound. Magnesium is also used to dehydrate oils, to form the Grignard reagent so important in organic chemistry, and as a deoxidizer in making certain alloys. The element is essential to both animal and vegetable life. MgO and $MgCO_3$ are used in ceramics, while several magnesium compounds are important medicinally. Only silver, copper and aluminum have a greater electrical conductivity than magnesium. Aluminum has also greater mass conductivity. During the war production of the metal was greatly increased to supply the needs for pyrotechnics, incendiaries, and aircraft. Peacetime uses, such as in garden tools, bicycles, rotating and reciprocating parts in machinery where lightness is desired, are finding ever greater acceptance. The price of the metal in ingot form is about 27¢ per pound (59¢ per kilogram).

MANGANESE (L. *magnes*, magnet, as pyrolusite was formerly confused with iron ores which are magnetic). Ger. *Mangan*. Fr. *manganèse*. Manganese is a hard, brittle metal with a brilliant luster and a reddish tinge. In 1740 Pott showed that pyrolusite (MnO_2), contained no iron, and formed a series of well-defined salts. In 1774 Scheele proved that it contained a new element. Gahn was the first to isolate the metal. Manganese is quite widely distributed in the combined state in such ores as pyrolusite (MnO_2), braunite (Mn_2O_3), and hausmannite (Mn_3O_4), as well as in the form of the sulfide, sulfate, carbonate, silicate, and tungstate. The metal can be prepared by reducing the oxides with carbon or aluminum; by reducing the halogen salts with sodium, magnesium, or aluminum; by reducing a manganese solution with various metals; and by electrolysis. The most important use of manganese is in the alloys ferromanganese and spiegeleisen in which form it is added to steel to impart toughness and hardness without brittleness. Manganese is essential to plant and animal life and to reproduction in animals. The oxide MnO_2 is used in the manufacture of chlorine and iodine, in making a black enamel for pottery, as a drier for oils, and as a depolarizer in dry cells; $MnCl_2$ is used in dyeing cotton; $MnSO_4$ is employed in calico printing; $KMnO_4$ and $NaMnO_4$ are used as disinfectants and in analytical chemistry. The chemical industry uses about 10% of the

mixed carbonyls which are then decomposed by heating. Nickel is magnetic at ordinary temperatures but not at 360°C. Air and sea water have very little effect on nickel, nor do hydrochloric or sulfuric acids corrode it at ordinary temperatures. At a red heat, nickel slowly decomposes steam. The addition of up to 18% of tungsten greatly increases the resistance of nickel to corrosion. Nickel is widely used as a catalyst, since in the finely divided state it speeds up many reactions such as the hydrogenation of oils, the reduction of nitrogen oxides to ammonia, the decomposition of acetylene, etc. Nickel plated objects are very common, as are alloys of nickel such as invar, German silver, constantin, chromel, monel metal, etc. Nickel steels are much used because of their toughness and resistance to corrosion. Nichrome and chromel are the most widely used alloys in the manufacture of electrical heating units. Nickel was so necessary during the war that it was one of the first metals to be put on the priority list and one of the last to be taken off. Nickel and nickel bronze or other nickel alloys are used as coinage in several countries. Edison cells use nickel oxide or hydroxide for depolarizing electrodes. Nickel usually behaves as a bivalent element, the trivalent salts being unstable as a rule. NiO, Ni_2O_3, $NiCl_2$, $Ni(OH)_2$, NiS, $NiSO_4$, and $Ni(NO_3)_2$ are common nickel salts. The wholesale price of nickel is about 60¢ per pound ($1.32 per kilogram).

NIOBIUM (Gr. myth. Niobe, daughter of Tantalus, as it is always found associated with tantalum). Ger. *Niobium*. Fr. *niobium*. Niobium is a platinum-white metal with a bright luster. It was discovered in 1801 by C. Hatchett. Niobium does not occur in the free state and its minerals are relatively rare. It is generally found with tantalum as the niobates and tantalates of calcium, iron, uranium, manganese, and the rare earths. The two metals are separated by taking advantage of the different solubilities of potassium fluotantalate and potassium fluoniobate. Niobium is malleable and ductile, and very resistant to corrosion, withstanding the action of the common mineral acids including aqua regia, although it is dissolved by hydrofluoric acid. An alloy containing 0.5% to 0.8% of niobium is used in engine parts which are subjected to temperatures in excess of 800°C. Like its companion metal, tantalum, a niobium electrode acts as an electrolytic valve allowing an alternating current to pass only in one direction through an electrolytic cell. Niobium has been used in lamp filaments and in jewelry, it being capable of being colored by an electrolytic process. Niobium forms the oxides Nb_2O_3, NbO_2 and Nb_2O_5, the pentoxide giving rise to salts known as niobates. NbF_5, $NbCl_3$, $NbCl_5$, and $NbOCl_3$ are other compounds. The wholesale price is about $75 per pound ($165 per kilogram).

NITROGEN (L. *nitro*, native soda; *gen*, forming). Ger. *Stickstoff*. Fr. *azote*, symbol Az, this symbol and J for iodine being the only instances of differences in national usage of chemical symbols. The compound PbN_6 is called lead azide even in this country, an example of the persistence of the old French name. Nitrogen is a colorless, odorless gas present in the atmosphere to the extent of 75.5% by weight, and 78.06% by volume. D. Rutherford, in 1772 is credited with its discovery, but Cavendish, Lavoisier and others investigated "phlogisticated air," as air minus oxygen was called. Nitrogen is a vital constituent of animal and plant diets, and forms a part of all living bodies. Certain legumes, notably beans, have the power of absorbing nitrogen from the air and transforming it into proteins which is in turn food for animals. This nitrogen cycle in the soil is essential to life. Fixed or combined nitrogen is present in many mineral deposits as saltpeter, KNO_3, or soda niter, $NaNO_3$. Because of its slight solubility in water, nitrogen is contained in many natural waters and has been found in the gases from springs, geysers, and volcanos. It is prepared by removing the oxygen and carbon dioxide from the air with hot copper and lime. This, of course, leaves the nitrogen contaminated with the inert gases. It may be prepared in the laboratory by heating an aqueous solution of a mixture of 1 mole $NaNO_2$ and ½ mole $(NH_4)_2SO_4$. Nitrogen has been made by the fractional distilla-

tion of liquid air, and by reactions with substances containing nitrogen of which the following equation is an example: $2NH_3 + 3Cl_2 = 6HCl + N_2$. Gaseous nitrogen is often used to form an inert atmosphere for the preservation of materials, and to fill incandescent bulbs, although the gas is not entirely inert since it combines directly with lithium, calcium, and magnesium when it is heated with these metals. Nitrogen is also used in the manufacture of ammonia, which may in turn be oxidized to nitric acid. Nitrogen compounds are very numerous, all nitrates, nitrites, nitrides, cyanides, cyanates, and all nitro, amino, and ammonium compounds being included in this category. Many nitrogen compounds are explosive, some, like picric acid, being comparatively stable, while others, like nitrogen iodide, can be exploded by touching them with a feather. Nitrogen forms five oxides; N_2O, NO, N_2O_3, NO_2, and N_2O_5. Ammonia, NH_3, nitric acid, HNO_3, and urea are perhaps the most important nitrogen compounds. It is an essential substance in time of war since nitrogen is the basis of every non-atomic military explosive, as well as an essential ingredient of fertilizer for the production of food. A cylinder of nitrogen containing 14½ pounds (6.6 kilograms) or 200 cubic feet (5663 liters) at normal pressure can be refilled for about $5.

OSMIUM (Gr. *osme*, a smell, from the odor of its volatile tetroxide). Ger. *Osmium*. Fr. *osmium*. Osmium is a brilliant metal of the platinum family, bluish in color and resembling zinc in appearance. It was discovered in 1804 by Tennant. It is a scarce element being found in nature alloyed with iridium in osmiridium, and in platinum sands in North and South America and the Urals. It may be precipitated from solution by H_2S as OsS_4, which on heating deposits osmium on the upper part of the crucible. Osmium may also be prepared by reducing OsO_4 with carbon monoxide or dioxide in a red hot porcelain tube. Osmium tetroxide melts at 45° and boils at 100°, yielding a very poisonous vapor which causes pathological disturbances even to the extent of blindness. Osmium has a specific gravity of 21.3 to 24 and has the greatest density of any known substance. It is harder than glass and is very brittle. The metal is readily dissolved by fuming nitric acid, aqua regia, or fused sodium or barium nitrate; it is also attacked by hot fluorine or chlorine. In the finely divided form osmium is a very effective catalyst, causing hydrogen and oxygen to explode at 40 to 50°. With an osmium catalyst ammonia can be made from its elements at 185 atmospheres and a temperature of 880 to 1000°. Its chief use is in the alloy osmiridium which is used to make pen points. Replacing jewels, alloys of osmium are used to make bearings for small instruments. Osmium is the only element which forms definite compounds with a valence of eight. It also forms salts in which it has valencies of 2, 3, 4, and 6. $OsCl_2$, $OsCl_3$, H_2OsO_4 and OsO_4 are typical compounds. Osmium sells for about $150 per troy ounce ($4.82 per gram).

OXYGEN (Gr. *oxyx*, sharp; *gen*, born). Ger. *Sauerstoff*. Fr. *oxygène*. Oxygen is a colorless, odorless, active gas. The liquid and solid forms have a pale blue color. It was discovered independently by Priestley and Scheele in 1774, and was known to the chemists of the 18th century as "dephlogisticated air." Oxygen is the most abundant element, making up 88.8% of the waters of the earth, 46% of the rocks and soils, and one-fourth of the atmosphere by weight or one-fifth by volume. The best commercial method of preparing oxygen is by the fractional distillation of liquid air but it can also be obtained by the electrolysis of water containing dissolved electrolyte, or by heating HgO, BaO_2, $KClO_3$ or other oxygen-containing compounds. Oxygen is not combustible but supports combustion, and combines with all the elements except the inert gases of the argon group. All plant and animal life as we know it depends on oxygen either free or combined for its existence. The gas is used in the oxy-hydrogen and oxy-acetylene flames for welding; for ventilating submarines; for medical purposes; for oxidizing oils, etc.; for bleaching; and in determining the carbon content of steel and organic compounds. The element exists in two forms, the usual state being O_2, while ozone, a less common form is

O_3. The name *ozone* was derived from a Greek word meaning "I smell"; the characteristic odor of the substance is often noticed around electrical machines. It is formed whenever an electric spark is produced and can often be observed during thunder storms. Ozone is a very active oxidizing agent especially towards organic matter and is used as a bactericide in sterilizing water as well as in other oxidizing and bleaching processes. Much of the ageing of rubber is caused by ozone in the atmosphere. Ozone is never sold as such but is made by an electric spark discharge at the place where it is to be used. A cylinder of oxygen holding 244 cubic feet (4905 liters) at normal pressure can be refilled for $7.50.

PALLADIUM (Named from the planetoid Pallas). Ger. *Palladium*. Fr. *palladium*. Palladium is a silvery white metal, less ductile but harder than platinum. It was discovered by Wollaston in 1803 and occurs native alloyed with platinum or gold, and as the selenide. It is a scarce element being present as an impurity in the nickeliferous ores of Sudbury, Ontario, from the matte of which it is sometimes isolated. Palladium may be separated from the platinum group through precipitation as the iodide by adding potassium iodide to the solution. The metal is obtained by reduction of its salts with hydrogen, or by deposition from its solutions in the presence of zinc. Palladium occludes gases to a remarkable degree, especially hydrogen, and like other members of the platinum family, it is a very good catalyst, particularly when in a finely divided state. It is attacked by hot, concentrated acids and by fluorine or chlorine at high temperatures. Alloys of palladium and gold are useful as platinum substitutes and, because of their resistance to atmospheric corrosion, are used for astronomical and dental purposes and for coating the reflectors of searchlights. Palladium salts are used in photography. Palladium functions as a bi-, tri-, and tetra-valent element. $PdCl_2$, K_2PdCl_4, $PdCl_3$, PdO, $Pd_2O_3{\cdot}xH_2O$, and $PdO_2{\cdot}xH_2O$ are typical palladium compounds. The metal sells for about $24 per troy ounce (77¢ per gram).

PHOSPHORUS (Gr. *phosphoros*, light-bringer). Ger. *Phosphor*. Fr. *phosphore*. Phosphorus is a non-metallic element occurring in several different forms. White or colorless phosphorus, the ordinary form, turns yellow on exposure to light. Red phosphorus can be made by heating the white variety or exposing it to a bright light. When a solution of yellow phosphorus in phosphorous tribromide is held at 180°, a bright red precipitate separates. This is called scarlet phosphorus. Metallic or violet phosphorus is obtained by heating the red variety in contact with lead for ten hours at about 500°C., the phosphorus dissolves in the lead and, on cooling, separates in this crystalline modification. Only the red and yellow forms are commercially available. When pure, the red form is not poisonous whereas the yellow variety is extremely toxic. Many of the compounds of phosphorus are harmless. Phosphorus, first isolated from urine by H. Brandt in 1669, is the first element whose discoverer is known. Phosphorus does not occur native but its compounds are widely distributed. The chief source of the element is phosphate rock, generally $Ca_3(PO_4)_2$, which is treated with sulfuric acid to convert it to phosphoric acid which is then heated with carbon, the crude phosphorus being removed by distillation. It occurs in all fertile soils, being a necessary factor in plant and animal economy. It is an essential constituent in protoplasm, nervous tissue and bones, occurring in the latter as calcium phosphate. Phosphorus is used in making bronzes, in gas analysis, in medicine, in making matches, and as a "getter" in incandescent lamp manufacture. PH_3, PCl_3, PCl_5, $POCl_3$, Na_3PO_4, P_2O_3, and P_2O_5 are typical compounds. In large quantities the red and the yellow varieties sell for 45¢ and 43¢ per pound (99¢ and 95¢ per kilogram) respectively.

PLATINUM (Spanish *plata*, silver). Ger. *Platin*. Fr. *platine*. Platinum is a tin-white metal, malleable, ductile, and harder than silver; it does not tarnish in air or dissolve in any single acid. It was first brought to Europe from South America in 1735. The metal occurs native, either in a fairly pure state or

alloyed with other metals and nuggets weighing up to 21 pounds have been found. In refining crude platinum, the metal is precipitated as $(NH_4)_2PtCl_6$ which on being heated yields spongy platinum. This is then rolled or hammered into the desired condition. Platinum is a very noble metal being dissolved only by aqua regia but it is corroded by the halogens and caustic alkalies. Like all the metals in this group, platinum possesses considerable catalytic activity, a property most pronounced when the metal is in a finely divided state. Platinum black, in which form it is generally used as a catalyst, is a fine, soft, black powder which is thought to be $PtO \cdot H_2O$. A platinum catalyst is used in the contact process for manufacturing sulfuric acid and other commercial reactions. Platinum is used for jewelry, and for electrical and dental purposes, as well as making crucibles, tongs, pyrometers, electrical contact points, pins, foil and plate. Another use in recent years is in decorating glassware, in which a platinum resin is applied and fired, leaving a bright and very thin coating of platinum. Very fine platinum nozzles, called spinnerets, are used to produce rayon, spun glass and other synthetic fibers. The chemical industry uses about 13% of the platinum produced. The most important war use is in the catalytic production of nitric acid which is so essential in explosives manufacture. The principal sources of the metal are Canada, Russia, South Africa, and Colombia. $PtCl_2$, H_2PtCl_4, $PtCl_4$, K_2PtCl_6, and $PtO \cdot 2H_2O$ are typical platinum compounds. The price of the metal is about $93 per troy ounce ($3 per gram).

PLUTONIUM (Being the second trans-uranium element, it was named for Pluto, the second trans-Uranus planet). This element, No. 94, was discovered by workers in the Radiation Laboratory in Berkeley, California. An isotope of atomic weight 238 was first detected by McMillan, Kennedy, Seaborg, and Wahl in 1940–41. The most important isotope, atomic weight 239 and half-life of 24,100 years, was found by Kennedy, Seaborg, Segre, and Wahl. This isotope was prepared in large quantities by neutron capture in the uranium pile. Like U-235 it is able to sustain a nuclear chain reaction and was the material used in the atom bomb. Plutonium is very similar chemically to uranium and neptunium. In fact, the elements from numbers 89 through 101 are considered as forming the actinide series of elements similar to the lanthanide or rare earth series. There is evidence that this number may be extended to 103 as the entire 5f subshell corresponding to the 4f shell in the rare earths is filled. All four valence states of plutonium, namely 3, 4, 5 and 6, can coexist in equilibrium in the same solution but the trivalent form is more stable than in the cases of uranium and neptunium. Eleven isotopes of plutonium are known with half-lives ranging from 22 minutes to 5×10^5 years. Adequate precautions must be observed in working with plutonium for even Pu-239 with a half-life of more than 24,000 years has the high specific radioactivity of 140,000,000 alpha disintegrations per milligram per minute.

POLONIUM (Named for Poland, the native country of its discoverer). This radioactive element was discovered by Mme. Curie in 1898 and was obtained by separation with bismuth from pitchblende. It is also known as *radium F* and is similar to the *dvitellurium* predicted by Mendeleev in 1891. This element, No. 84, is extremely scarce and none of its salts has been isolated.

POTASSIUM (Eng. *potash*. Symbol K from *kalium*). Ger. *Kalium*. Fr. *potassium*. Potassium is a light, silver-white alkali metal, first isolated in 1807 by H. Davy. It is found in nature in large quantities but only in the combined form. It occurs in sylvite (KCl), saltpeter (KNO_3), and many other minerals. Potassium salts are necessary to plant life and are therefore found in all fertile soils. Plants preferentially absorb these salts which are then found in the ash they leave on ignition. The metal is produced by the electrolysis of fused potassium hydroxide but it is seldom made as it has few uses. Like all of the alkali metals it tarnishes in air, combines with water at

ordinary temperatures, and hence must be preserved under kerosene. An alloy of sodium and potassium which is a liquid at ordinary temperatures is used in high reading thermometers. Potassium is used in certain photoelectric cells and in analysis for the determination of oxygen. Potassium has a valence of one in all of its compounds. KOH, KCN, KCl, KBr, KI, K_2SO_4, KNO_3, K_2SiO_3, K_2CO_3, K_2CrO_4, and $K_2Cr_2O_7$ are some of the more important potassium compounds. The metal retails for about $12.50 per pound ($27.50 per kilogram) but many of its compounds are comparatively cheap. For example, potassium chloride costs only 15¢ per pound (33¢ per kilogram) wholesale.

PRASEODYMIUM (Gr. *praseos*, leek-green, and *didymos*, a twin). Ger. *Praseodym*. Fr. *praséodyme*. Praseodymium is a rare earth metal that has a yellow tinge and is strongly paramagnetic. It was discovered in 1885 by C. A. von Welsbach. The element is widely distributed but in rather small amounts. A mixture of praseodymium and neodymium was for a long time considered to be an element and was called *didymium*. The ratio of praseodymium to neodymium in most minerals is about 1 to 2, both metals being found in cerite and other rare earth minerals. A little didymia is used to impart a brown color to printed matter on gas mantles. Praseodymium salts are leek-green in color. Compounds of this metal are Pr_2O_3, PrO_2, $PrCl_3$, $Pr_2(SO_4)_3$.

PROMETHIUM (Named for Prometheus, the fire-bringer of Greek mythology). This name for element No. 61 was proposed by Coryell, Marinsky and Glendenin of the Clinton Laboratories at Oak Ridge, Tenn. This group was the first to make a quantitative investigation of the element. Milligram quantities of the yellow chloride and the rose nitrate have been prepared. Promethium is the fifth element in the rare earth series. Its identification filled the last gap in the periodic system, its presence having been predicted by many earlier workers. It forms salts such as $PmCl_3$ and $Pm(NO_3)_3$.

PROTACTINIUM (Gr. *protos*, first). Ger. *Protaktinium*. Fr. *protactinium*. Protactinium is one of the four radioactive atomic species representing element 91 and is the only one that can be isolated in weighable quantities. The first isotope, UX_2 or brevium (half life 1.14 minutes), was discovered by Fajans in 1913. Protactinium itself was discovered in 1917 by Hahn and Meitner and independently and at about the same time by Soddy and Cranston. It is the mother substance of actinium and its series of natural radioactive elements, being itself derived from an isotope of uranium (actino-uranium). One ton of uranium in any natural ore contains about 0.27 grams protactinium. The oxide Pa_2O_5 was first isolated in 1927, the metal itself in 1934. The atomic weight of the element was listed for the first time in the International Atomic Weight Table of 1936.

RADIUM (L. *radius*, ray). Ger. *Radium*. Fr. *radium*. Radium is a radioactive element. It has been prepared as a white metal which immediately becomes black on exposure to air. The metal will decompose water in the cold, and blackens organic matter such as paper on contact. It was discovered in 1898 by P. Curie and his wife, M. S. Curie. Radium is a decomposition product of uranium, and is always found with that metal, generally to the extent of about one part in three million. Although properly considered a rare element yet, if the amount of it estimated to be present in the outermost mile of the earth's land area were concentrated in a single cube, such a cube would measure 500 feet on a side. The most important source is the pitchblende found at Great Bear Lake in northern Canada, where more than 100 grams of radium are extracted annually. Another important source of radium is the carnotite sand of Colorado. The element is constantly giving off heat, the temperature of radium and its salts being about a degree and a half higher than

that of its surroundings. During 2300 years of its life a gram of radium gives off 250,000 times as much energy as the burning of a gram of coal. Each gram of radium produces about a tenth of a cubic millimeter of emanation each day. This gas is pumped off and sealed in tiny tubes which are applied to the diseased tissue when radium is used to combat cancerous growths and skin diseases. Radium and its salts are extremely poisonous to all life; the unskillful application of the radiation is very dangerous. The radium of commerce is generally in the form of the chloride or bromide. The final decomposition product of radium is an isotope of lead. The carbonate and sulfate are used in luminous paints. The price of radium was about $20,000 per gram in 1938 but it is no longer quoted on the open market.

RADON, NITON or RADIUM EMANATION (The name *radon* was chosen because it comes from radium. The name *niton* is from L. *nitens*, shining). Ger. *Niton*. Fr. *niton*. Radon is a gaseous substance emanating from radium and having radioactive properties of its own. It was discovered in 1900 by Dorn but was observed at about the same time by the Curies, Gray, Rutherford and Ramsay. The gas appears to be inert and a member of the argon family and has been liquefied and solidified by Rutherford, Ramsay and others. It decomposes into a radioactive solid and alpha particles, each of which is an atom of helium carrying two unit positive charges. For the method of using radon, see *radium*.

RHENIUM (Named from the Rhine province belonging to Germany). Ger. *Rhenium*. Rhenium is a member of the manganese family of metals and was once called dwimanganese. It was discovered by Noddack, Tacke, and Berg in 1924, at the same time that they discovered masurium or ekamanganese (i.e., technetium). Both of these metals are found in the combined state in platinum ores, gadolinite, molybdenite, and sperryite. Rhenium is a rare element. The metal is stable in air and possesses a very high melting point and boiling point. The most stable rhenium compounds are those in which the element has a valence of six or seven. Re_2O_7, $HReO_4$ (a strong acid), $KReO_4$, $ReCl_6$, Re_2S_7, ReS_3, ReS_2, ReO_2, and ReO_3 are known. The metal is being prepared in Germany to the extent of about 150 kilograms a year. Rhenium, which has some unusual electrical properties including a conductive oxide, may find use in electronic applications when better methods for its purification have been developed. Platinum-rhenium thermocouples have been made, and the metal may find some use as a catalyst. The price is about $4 per gram.

RHODIUM (Gr. *rhodon*, a rose, from the color of the aqueous solutions of its salts). Ger. *Rhodium*. Fr. *rhodium*. Rhodium, a silvery white metal of the platinum family, was discovered in 1804 by Wollaston. It occurs as an alloy in platinum ores, in osmiridium, and in the gold-rhodium alloys known as rhodite, which are from 30 to 43% rhodium. It is considered a rare element. The metal is insoluble in acids or aqua regia but when fused with potassium acid sulfate it yields the sulfate. An alloy of 95% platinum and 5% rhodium is superior to platinum for making crucibles and other laboratory equipment. Pure rhodium is attacked by chlorine or sulfur more readily than is any other metal in the platinum group. Rhodium is never used in the pure state except as an electrodeposited coating on other metals. Usually plated from phosphate or sulfate solution, rhodium coatings are harder than those of any other precious metal. Rhodium is superior to chromium when used in searchlight and projection reflectors. The presence of rhodium adds hardness to platinum or palladium. For this reason it is used in the spinnerets for making rayon and glass fibers. Rhodium is used in conjunction with platinum to make thermocouples. Rhodium black, a finely divided substance containing some oxide or hydride, is used as a catalyst and for producing a black color in decorating porcelain. A new use for rhodium is in plating standard weights. $RhCl_3$, $RhCl_3 \cdot xH_2O$, $Na_3RhCl_6 \cdot$

$18H_2O$, Rh_2O_3, RhO_2, Na_2RhO_4 are typical compounds. The price is about $125 per troy ounce ($4 per gram).

RUBIDIUM (L. *rubidus*, red). Ger. *Rubidium*. Fr. *rubidium*. Rubidium is a silvery white alkali metal resembling potassium. It inflames spontaneously in air and must be preserved out of contact with air and water. Rubidium is the second most electropositive metal being exceeded only by cesium in this respect. It was discovered spectroscopically in 1860 by Bunson and Kirchhoff and is present in several rare minerals, the chief source being the mother-liquors from carnotite refineries. There are no rich deposits but the element is widely distributed. Its salts impart to the nonluminous flame a very brilliant red color. The metal is softer than any metal except cesium and forms a series of salts such as RbCl, $RbNO_3$, Rb_2SO_4, Rb_2O, etc. Rubidium and its salts have no important uses although the metal has been used in photoelectric cells. The price is about $80 per troy ounce ($2.57 per gram).

RUTHENIUM (*Ruthenia*, Russia). Ger. *Ruthenium*. Fr. *ruthénium*. Ruthenium is a hard, brittle metal of the platinum family, resembling platinum in luster and appearance. The element was named by Osann who discovered it in 1828. It was first made in the pure state by Klaus in 1845. Ruthenium is a very scarce element. It occurs in the rare mineral laurite, Ru_2S_3, but it is obtained from osmiridium in which it occurs as an impurity to the extent of 6% or less. Ruthenium has several different valencies in its various compounds, $RuCl_2$, $RuCl_3$, K_2RuCl_5, K_2RuCl_6, Ru_2O_3, RuO_2, and $K_2RuO_4 \cdot H_2O$ being typical ruthenium salts. The metal occludes gases and is sometimes used to catalyze oxidation reactions. Ruthenium is of little commercial importance although it is sometimes used as an alloy with other platinum group metals. It costs about $35 per troy ounce ($1.13 per gram).

SAMARIUM (Named after *Samarski*, a Russian engineer). Ger. *Samarium*. Fr. *samarium*. Samarium is a hard, brittle, yellowish-gray, lustrous metal which quickly tarnishes in air. It was discovered in 1879 by Lecoq de Boisbaudran and, like the other rare earths, is found in small quantities in such minerals as cerite, gadolinite, samarskite and others. It may be separated from lanthanum, praseodymium, and neodymium by converting the mixed oxides to the anhydrous chlorides and passing in a stream of dry hydrogen at a red heat thus converting the samarium to $SmCl_3$. This is insoluble in alcohol whereas the chlorides of the others are soluble. Samarium salts are pale yellow in color. They have a small use as activators in fluorescent powders. The usual compounds of samarium have been prepared, including Sm_2O_3 or samaria, Sm_2S_3, $Sm_2(SO_4)_3$, $SmCl_3$, $Sm(NO_3)_3 \cdot 6H_2O$ and others.

SCANDIUM (Named after the Scandinavian peninsula by its Swedish discoverer). Ger. *Scandium*. Fr. *scandium*. Scandium itself has not been isolated, but the properties of its salts prove it to be identical with the ekaboron predicted by Mendeleev. It was discovered in 1879 by L. F. Nilson and is found in a few rare minerals such as wolframite, wiikite and euxenite to the extent of one or two percent Sc_2O_3. $ScCl_3$, $ScBr_3 \cdot 6H_2O$, Sc_2O_3 or scandia, Sc_2S_3, $Sc(OH)_3$, $Sc_2(SO_4)_3$ and many other scandium compounds have been prepared.

SELENIUM (Gr. *selene*, the moon). Ger. *Selen*. Fr. *sélénium*. Selenium is a non-metallic element which exists in several allotropic forms. It was discovered in 1817 by J. J. Berzelius and J. G. Gahn. Selenium is found in many sulfide ores generally in the form of selenides but sometimes native. The most common ore is clausthalite, PbSe, and the element may be obtained from the flue dust of pyrites burners. Annual world production of selenium is about one million pounds, almost entirely as a by-product of electrolytic refining of copper. It is a rather scarce element. The element

is said to be contained in teeth and bones and in most vegetables, especially spinach. It is precipitated from its solutions by sulfur dioxide, which is the method generally used to obtain the element from its refined ores. Selenium exists in several allotropic forms including an amorphous form resembling plastic sulfur. The stable form at ordinary temperatures, gray selenium, is the most dense and is semimetallic in appearance. Crystalline red selenium exists in two monoclinic forms which may be obtained by evaporation of carbon disulfide extracts of amorphous red selenium. Amorphous selenium occurs as black, vitreous selenium, amorphous red selenium, or red colloidal selenium. These forms result when liquid selenium is rapidly cooled or when elementary selenium is formed in reduction reactions. All amorphous forms and both monoclinic crystalline forms are transformed to gray selenium when heated. The electrical conductivity of the element is not large in the dark but it may be increased several hundredfold on exposure to light. It is this property of gray selenium which furnishes the basis for its use in photoelectric cells. These cells are of rapidly increasing importance in controlling automatic equipment of many kinds. Selenium has also been used in rectifiers of electric current which exhibit remarkable stability under high overloads and this use reached such industrial and military importance as to dislocate the U. S. market and to bring about government control of distribution. The thermal properties of such rectifiers makes them useful as voltage-sensitive resistors as well as temperature-sensitive resistors. Selenium is used in preparing a scarlet-red color for glass, glazes and enamels; for making flameproof insulated wires and paper; in the colloidal form as a germicide and fungicide. Selenium sulfide test papers may be used to detect atmospheric concentrations of mercury as low as or lower than 150 micrograms per cubic meter. Selenium itself is not poisonous but the alkali selenites and selenates are very toxic. When warmed, selenium emits an odor resembling that of rotten radishes. Selenium and its compounds impart a blue color to the Bunsen flame. The element resembles sulfur and has valencies of 2, 4, and 6. SeO_2, Na_2SeO_3, Na_2SeO_4, and Na_2Se are typical selenium compounds. Selenium dissolves in alkali metal sulfites to form selenosulfates (Me_2SeSO_3) and since tellurium does not undergo this reaction this property gives a method of separation of these two elements. It is sometimes used to replace sulfur in special vulcanizing applications particularly in connection with synthetic rubbers. It has wide use as an alloying ingredient in stainless steel, copper alloys and invar. The United States and Canada are the best sources. The price is about $5 per pound ($11 per kilogram).

SILICON (L. *silex*, flint). Ger. *Silicium*. Fr. *silicium*. Silicon is a non-metallic element which is dark, steel-gray when crystalline and a dark brown mass when amorphous. It was first isolated in 1823 by J. J. Berzelius. Silicon is never found native but its compounds are so common that silicon ranks second only to oxygen in abundance composing 25.8% of the known land, sea and air. It occurs in all silicate minerals as well as in quartz (SiO_2), sandstone, and others. The silicates include clay, granite, feldspar, mica, and many other very common minerals. Silicon is made by reducing SiO_2 with magnesium or sodium. It is employed as a deoxidizer in metallurgy where many silicon alloys are used, the silicon being added as a rule in the form of ferrosilicon. High silicon alloys are very hard and chemically resistant, but are so brittle they cannot be machined. Silicon, like germanium, is a semiconductor. When exactly measured traces of certain impurities are added to exceptionally pure silicon, the ability to control current is acquired. Transistors made from such material can operate up to 200°C. whereas germanium transistors have a temperature limit of 100°C. Silica, or SiO_2, is used in making glass, mortar, and Portland cement; sodium silicate under the name of waterglass is used as a medium for preserving eggs and as an adhesive. Silicon is very resistant to acid corrosion, a property which is also manifested by the high silicon alloys. A very interesting series of compounds known as silicones are made by dehydration and polymerization of $(CH_3)_2Si(OH)_2$ and similar compounds. These substances, some of which resemble rubber, have remarkable heat-resistant qualities. SiO_2, SiH_4, Na_2SiO_3 and K_2SiO_3 are well-

known silicon compounds. The price of silicon of 97% purity is about 18½¢ per pound (41¢ per kilogram) although SiO_2 of 99½% purity is only $20 per ton ($22 per metric ton). Because its purification is so difficult, semiconductor grade silicon costs about $380 per pound.

SILVER (Assyrian, *sarpu*. Anglo-Saxon *soelfor*. Symbol Ag from L. *argentum*). Ger. *Silber*. Fr. *argent*. Silver is the whitest of metals and the best conductor of heat and electricity. It is strong and is excelled only by gold in malleability and ductility. Silver is sometimes found free in nature and has been known from the earliest times. Most silver ores contain only about one percent of silver but such ores are fairly common. Mexico and the United States produce most of the world's silver, a great deal being a by-product in the refining of lead and copper. It is a scarce metal. The silver ion is very poisonous and like lead is cumulative in action. Silver is stable in air and water but blackens on exposure to vapors of sulfur compounds especially hydrogen sulfide which form the sulfide, Ag_2S. The metal is used in making tableware, coinage, jewelry, and in silvering mirrors. Certain of its salts, particularly the halides, are sensitive to light and are much used in photography. Silver nitrate is used in analytical chemistry, in medicine and, with the cyanide, in plating. In recent years steels containing silver have been widely used in making pistons for gasoline engines. Silver solder is used in low temperature brazing. Large quantities of silver, mostly as bus bars, were used in the atom bomb project, and it was used to plate some of the equipment for the manufacture of penicillin. Perhaps the most important use of silver in the war was as a substitute metal. Used in place of copper, nickel, chromium, aluminum and tin, it released thousands of tons of these metals for vital war use. The price of silver is about 78¢ per troy ounce (2.2¢ per gram).

SODIUM (Eng. *soda*). Ger. *Natrium*. Fr. *sodium*. Sodium is a waxy, silvery white alkali metal. It was first isolated in 1807 by H. Davy. Sodium always occurs in the combined form and is present as the chloride in vast quantities in sea water and rock salt deposits. In Chile and Peru there are deposits of $NaNO_3$, and on the sites of dried-up lakes there are found carbonates, sulfates, and borates of sodium. Sodium salts are present in nearly all brines, in animal fluids and in most plants. Metallic sodium is attacked by air and water, hence it is usually preserved under kerosene or imbedded in petrolatum. It is prepared commercially by the electrolysis of fused sodium hydroxide and is used in making the peroxide and cyanide, as well as in the manufacture of some aniline dyes and a number of other organic compounds where a very strong reducing agent is required. It is sometimes used in the preparation of other metals. Large quantities of sodium are now used in the manufacture of tetraethyl lead, as a heat transfer medium in the valves of internal combustion engines, and as a scavenger and alloying ingredient in metallurgy. Sodium and its salts impart a brilliant yellow color to the flame. Many sodium compounds are extremely important often being sold by the carload. A few of the most important are the chloride, NaCl, which is a necessary constituent of animal diets; caustic soda, NaOH; soaps, which are sodium or potassium salts of one or more fatty acids such as stearic, oleic or palmitic; borax, $Na_2B_4O_7 \cdot 10H_2O$; trisodium phosphate, $Na_3PO_4 \cdot 12H_2O$; hypo, $Na_2S_2O_3 \cdot 5H_2O$; soda ash, Na_2CO_3, and sal soda, $Na_2CO_3 \cdot 10H_2O$; Glauber's salt, $Na_2SO_4 \cdot 10H_2O$; baking soda, $NaHCO_3$; $NaNO_3$; $NaNO_2$; Na_2O_2; the various silicates which are different ratios of Na_2O, SiO_2 and H_2O; and the sulfite Na_2SO_3. The wholesale price of metallic sodium is about 16¢ per pound (35¢ per kilogram) but rock salt can be bought for as little as 1¢ per pound (2.2¢ per kilogram).

STRONTIUM (Named from the town of Strontian, Scotland). Ger. *Strontium*. Fr. *strontium*. Strontium is a silvery white metal but appears yellow when contaminated with nitride or silicide. This metal of the alkaline earth group was first isolated in 1808 by H. Davy

although the oxide was known to Crawford in 1790. It is never found native, occurring chiefly as strontianite ($SrCO_3$), and celestite ($SrSO_4$). Strontium metal has no commercial uses but, like the other alkaline earth metals, it can be prepared by the electrolysis of the fused chlorides. Strontium salts impart a brilliant red color to a flame, and are used in fireworks, red signal flares and on tracer bullets. Strontia (SrO) is used in the recovery of sugar from beet-sugar molasses. A mixture of calcium, barium and strontium carbonates are used to emit electrons in fluorescent lamps. Some strontium compounds have limited uses in medicine. Strontium has a valence of 2 and forms compounds such as $SrCl_2$, $SrBr_2$, and $Sr(NO_3)_2$. The metal retails for about $5 per ounce (18¢ per gram), but the wholesale price of the nitrate is only 11¢ per pound (24¢ per kilogram).

SULFUR (Sanskrit, *solvere*. L. *sulphurum*). Ger. *Schwefel*. Fr. *soufre*. Sulfur, a non-metallic element that is found native as well as combined, has been known from very early times. It exists in several allotropic forms of which the most common is rhombic sulfur, the variety which is found native and is mined in vast quantities in Texas, Louisiana and Sicily. Sulfur compounds such as the metallic sulfides and sulfates are also very common. Rhombic sulfur is a yellow powder which changes in shade with different temperatures. When molten sulfur is allowed to cool slowly, wax-yellow needles of monoclinic sulfur are formed and these change to rhombic sulfur at ordinary temperatures. Another form sometimes encountered is nacreous sulfur which forms yellowish-white needles with a pearly luster. Other less common metastable varieties as well as certain amorphous types are also known. Flowers of sulfur is the name given to a finely divided form prepared by sublimation. In the United States, sulfur is mined by the very unusual method of drilling to the sulfur stratum and sinking three concentric pipes down to the deposit. Superheated steam is then forced down the outside pipe and melts the sulfur; hot water is pumped down the other outside pipe at high pressure, whereby the molten sulfur is forced up through the middle pipe and is collected at the surface. Sulfur is used in the manufacture of matches, gunpowder and pharmaceutical preparations, as well as in the vulcanization of rubber and as a fungicide. Most of the sulfur produced is burned to sulfur dioxide which is the intermediate in the preparation of sulfuric acid, sodium thiosulfate, calcium bisulfite, and other sulfur compounds. Sulfur is one of the elements essential to plant and animal life. It is a constituent of some proteins. An important sulfur compound is hydrogen sulfide, a common laboratory precipitant which is very poisonous. Sulfur has valencies of 2, 4, and 6. FeS, $BaSO_4$, $CaSO_3$, BaS, SO_2, SO_3, S_2Cl_2, and $Na_2S_2O_3 \cdot 5H_2O$ are typical sulfur compounds. Crude sulfur in bulk sells for about $26.50 per long ton ($26.50 per metric ton) but U. S. P. flowers sell for about 4¢ per pound (8.8¢ per kilogram) and the commercial flour for about 2½¢ per pound (5½¢ per kilogram).

TANTALUM (Gr. myth. *Tantalus*, because the metal was hard to isolate, therefore tantalizing). Ger. *Tantal*. Fr. *tantale*. Tantalum is a bluish-gray metal with a bright luster and which is not affected by exposure to air. The element was discovered in 1802 by A. G. Ekeberg. It is never found in the free state but occurs with niobium as the tantalates and niobates of iron, calcium, manganese, uranium and the rare earths. It is a rare element. Tantalum is impervious to any single acid except hydrofluoric being unaffected by aqua regia but it will dissolve in the fused alkalies or in a mixture of nitric and hydrofluoric acids. Tantalum has high melting and boiling points, is malleable and very ductile, and was once used in making filaments for incandescent lamps but in this capacity it has been replaced by tungsten. Its main use is for chemical equipment especially for the production and handling of hydrochloric acid. It is also used in vacuum tubes and in surgery where, among other uses, it is made into skull plates. Tantalum is used to make pen nibs, dental and laboratory equipment, normal weights, and parts for delicate instruments which are subjected to the action

of corrosive gases. It is also used as a rectifier for alternating current since a tantalum electrode in a single cell will permit the current to flow only in one direction, thus changing an alternating current into a pulsating direct current. Tantalum usually has a valence of five. Ta_2O_5, TaO_2, $FeTa_2O_6$, $TaCl_3$, $TaOF_3$, $CaTa_2O_6$, $TaCl_5$, and K_2TaF_7 are typical tantalum compounds. The metal in the form of sheets or rods sells for about $39 per pound ($86 per kilogram).

TECHNETIUM (Gr. *technikos*, an art, as this was the first element to be made artificially). It was discovered in 1937 by Perrier and Segre in molybdenum bombarded in the Berkeley cyclotron with deuterons or neutrons. The discovery of this element in nature in 1924 under the name of "masurium" was announced by Noddack, Tacke and Berg coincidentally with their announcement of the discovery of rhenium. Other workers were unable to confirm their results and no chemical properties of masurium and its compounds were observed. It is generally recognized that Perrier and Segre were the first to actually observe this element and, consequently, their name of "technetium" is now official. The existence of technetium was to be expected ever since the first acceptance of the periodic system. First called "eka-manganese," it resembles manganese and, even more closely, rhenium. It is separated from molybdenum by precipitating the latter with oxyquinoline. A black sulfide, probably Tc_2S_7, has been prepared.

TELLURIUM (L. *tellus*, the earth). Ger. *Tellurium*. Fr. *tellure*. Tellurium is a non-metallic element of the sulfur-selenium family. It was discovered in 1782 by F. J. Müller (Baron von Reichenstein) and later confirmed by M. H. Klaproth who actually isolated the new element. When cooled from the molten state, tellurium is a tin-white crystalline mass which is brittle and easily powdered, and has a metallic luster. It also exists as a brownish-black amorphous powder. Tellurium is the least abundant of the sulfur family, rarely occurring native but usually as telluride and in a few oxidized ores. It is slightly more abundant than gold. Tellurium is used in the glass industry, in the manufacture of electrical equipment, and in making dyestuffs. Some of its alloys have valuable properties, that with tin being very hard and of high tensile strength, while its alloy with aluminum is very ductile. Colloidal tellurium is used as an insecticide, germicide, and wood preservative. Certain tellurium salts are used in staining metals, while one tellurium compound has been found to possess antiknock properties when used as a component of motor fuels. Tellurium is poisonous and is readily absorbed from gold-tellurium dental fillings. The very offensive "tellurium breath" is caused by the inhalation of the vapors of tellurium or by the absorption of the element in the body by other means. The element has valencies of 2, 4, and 6. H_2Te, H_2TeO_4, H_2TeO_3, $AuTe_2$, TeO_2, and $BaTeO_4$ are typical tellurium compounds. The wholesale price is about $1.75 per pound ($3.85 per kilogram).

TERBIUM (from *Ytterby*, a town in Sweden). Ger. *Terbium*. Fr. *terbium*. Terbium is a rare earth metal which has not yet been isolated. It was discovered in 1843 by C. G. Mosander and is one of the least abundant of the rare earths, being found in small quantities in gadolinite, cerite, and other rare earth minerals. Terbium salts are colorless or white and have no important uses. Tb_2O_3 or terbia, Tb_4O_7, $TbCl_3$, $Tb_2(SO_4)_3$, $Tb(NO_3)_3 \cdot 6H_2O$, and a few other terbium salts have been prepared.

THALLIUM (L. *thallus*, a budding twig). Ger. *Thallium*. Fr. *thallium*. Thallium is a gray metal, softer than lead, and having high malleability and low tenacity. In 1861 Crookes discovered a new green line in the spectrum which he attributed to a new element which he called thallium. The metal was first isolated in 1862 by A. Lamy. The ores of thallium are so scarce that it is easier to obtain the metal from the mud of

the lead chambers or the flue dust of sulfuric acid works. Thallium salts are poisonous and color the non-luminous flame a bright green. Thallium acetate, which is poisonous, when taken internally causes a falling out of the hair. Depilatory preparations containing up to 5½% have been prepared and sold but their use is attended by considerable danger. Thallium itself has no important uses, but its salts, especially the sulfate, are widely used in rat poisons, in a few medicinal preparations, in analytical chemistry, in photoelectric cells, and in making green signal lights. The element has valencies of 1 and 3. Tl_2O, Tl_2O_3, TlOH, TlCl, TlO(OH), and Tl_2S are typical compounds. Thallium costs about $12.50 per pound ($27.50 per kilogram).

THORIUM (Scandinavian myth. *Thor*). Ger. *Thorium*. Fr. *thorium*. Thorium is a metal resembling platinum in color, and having a high specific gravity and melting point. It was discovered in 1819 by J. J. Berzelius. Thorium is widely distributed but in small quantities, thorite, orangite, and thorianite containing from 50 to 78% ThO_2. The chief ore is monazite sand in which thorium is present to the extent of about 5 to 7% in the concentrated ore. The most important use of thorium is as the nitrate which is combined with about one per cent of cerium nitrate to make Welsbach gas mantles. These nitrates are burned to oxides the first time the mantles are used; beryllium and magnesium nitrates are also present to strengthen the ash skeleton. Certain thorium salts have some small use in medicine, analysis, and roentgenography. Thorium metal is used in the electronic industries for its thermionic emission properties, low work function, and action as a "getter." It is a very soft, ductile metal. Thorium is radioactive. It is a member of the tin group, and has a valence of four. ThO_2, $ThCl_4$, $Th(NO_3)_4$, $Th(OH)_4$, are typical compounds. Thorium undergoes fission when bombarded with high-speed neutrons, and was considered for use in the atom bomb. It can be converted into fissionable uranium 233. The price of the metal is about 40¢ per gram but the nitrate costs as little as $3.50 per pound ($7.70 per kilogram).

THULIUM (L. *Thule*, the most northerly part of the habitable world). Ger. *Thulium*. Fr. *thulium*. Thulium is a rare earth metal of the erbium group and has never been isolated. It was discovered in 1879 by P. T. Cleve and is found in small amounts in euxenite, gadolinite, blomstrandine, and other rare earth minerals. It is very difficult to separate thulium from the other metals of its group, especially erbium. Thulium salts are pale green in color. Tm_2O_3 or thulia, $TmCl_3 \cdot 7H_2O$, $Tm(NO_3)_3 \cdot 4H_2O$, $Tm_2(SO_4)_3$ and other thulium salts have been prepared.

TIN (Anglo-Saxon, Danish, and Icelandic, *tin*. Actual origin unknown). Ger. *Zinn*. Fr. *étain*. Tin is a white metal with a slight bluish tinge. Below 18°C. the stable form is *gray tin*, which is a powdery material and long exposure to cold will cause metallic tin to change to this gray form. When tin is so affected it is said to have the tin disease. When a piece of tin is bent it emits a high-pitched crackling noise known as the "cry" of tin. The metal was known in ancient times, for, although the ancients did not find it native, the smelting of tin is a comparatively simple process. Tin, though a common metal, is quite scarce, few workable deposits being known. It is less common than cerium, vanadium, zirconium and other metals that are usually thought of as rare. The most important ore is cassiterite, SnO_2. The ore is first concentrated, then roasted, and then impurities such as tungsten and iron are removed chemically. The best tin mines are in the Malayan peninsula but during the war these deposits were in the hands of the Japanese and this made Bolivia the next best source. It is widely used in lining vessels for domestic and industrial use, but tin foil has been almost completely replaced by aluminum foil in the wrapping of tobacco, candy, etc. Tin forms a part of many valuable alloys such as brass, bronze, pewter, solder, and white bearing

metal. The so-called "tin" cans are made of sheet iron coated with a thin layer of tin. The metal is also used as a reducing agent. Tin oxide (SnO_2) is used as a polishing powder and as an opacifying agent in glasses, glazes, and enamels. Tin sulfide is used as a bronzing powder and the two chlorides, $SnCl_2$ and $SnCl_4$, are used as mordants, in weighting silk, and in dyeing. Tin has valencies of two and four, and forms compounds such as SnO, SnO_2, $Sn(OH)_2$, H_2SnO_3, and $SnSO_4$. The price of tin is about 86¢ per pound ($1.90 per kilogram).

TITANIUM (L. myth. *Titans*, the first sons of the earth). Ger. *Titanium*. Fr. *titane*. Titanium is a metal of the tin group which resembles iron and takes a high polish. It was discovered in 1791 by W. Gregor, and rediscovered in 1794 by M. H. Klaproth who named it titanium. The metal does not occur free in nature and its compounds are not found in very concentrated form, yet it is more abundant than copper, lead, and zinc. Its most important ores are rutile, TiO_2, and ilmenite, $FeTiO_3$. Its commercially important deposits are world-wide. An important source is India where it occurs mostly as ilmenite. In the United States significant sources are in Florida, Virginia, New York and Wyoming. In Canada a major deposit supplies material to that country and the United States. The use of titanium as a structural metal has been retarded by the difficulty of freeing it from oxygen and nitrogen. The best method appears to be the chlorination of the oxide with subsequent decomposition by means of magnesium in an atmosphere of helium. The metal is hard and so brittle that in the cold it can be powdered in an agate mortar but at a red heat it can be forged. It burns in oxygen at 610°C. to form the oxide, TiO_2, and in nitrogen at 800°C. to form the nitride, TiN. This is the only known vigorous combustion in nitrogen gas. Titanium is chiefly used in metallurgy as a deoxidizer and denitrogenizer, and to add desirable qualities such as toughness and resistance to heat and corrosion to alloys. Titanium has great potential value as a structural meterial where weight, strength and corrosion resistance are important, particularly at intermediate temperatures. It is twice as heavy as aluminum but four times as strong. It is as strong as stainless steel but only half as heavy. The superiority of titanium is even more significant in the temperature range 200–400°C. Aluminum and magnesium alloys are virtually useless at 300°C. while titanium still retains an appreciable fraction of its room temperature properties. Needless to say it would be widely used but for the high cost of its metallurgical processing. The commercial production of the metal is rapidly expanding. The oxide (TiO_2) is a brilliant, white pigment that is used in the ceramic, rubber and other industries. Certain titanium compounds are used as incandescent media in illumination, while others are used as dyes and mordants for wool, cotton, and paper. During the war the tetrachloride was used to produce a white smoke and the oxychloride was blown into ships' fireboxes in powdered form to produce dense clouds of black smoke. The tetrachloride mixed with ammonia is used in sky writing. Other than those previously mentioned, Ti_2O_3, TiF_4, $TiCl_4$, and K_2TiF_6 are the most common titanium compounds. The price of the metal is about $5.00 per pound ($11.00 per kilogram) but the more easily produced TiO_2 costs only about 22½¢ per pound (50¢ per kilogram).

TUNGSTEN (Danish *tung sten*, heavy stone). Ger. *Wolfram*. Fr. *tungstène*. Symbol W (Wolframium). Tungsten is a metal of the chromium group. It is steel-gray in color, with a high metallic luster and good tensile strength, and has the highest melting point of any metal. It was discovered by Scheele in 1783 with the assistance of two laboratory helpers, the Spanish brothers J. J. and Don F. de Elhuyar. Many historians credit the de Elhuyars with the discovery of the metal. Tungsten does not occur native and its compounds are rather rare. The most important ores are the wolfram group (the iron and manganese tungstates) and the scheelite group (the calcium tungstates). Newly discovered tungsten deposits have made the United States nearly independent of foreign supplies but some is still imported from China (formerly our chief source), Ma-

laya, Bolivia, Portugal and other countries. Russia has large unworked deposits of tungsten. The ores are first refined to a content of about 65% WO_3 and are then given different chemical treatments depending on whether the oxide, the tungstates or the metal is wanted. Tungsten filaments are used in nearly all incandescent lamps, as well as in the wiring of electric furnaces; the metal is also used for targets in X-ray tubes, in contact points, and in phonograph needles. Tungsten alloys are used in tool steel and in other places where great strength and high heat-resisting qualities are needed. When tungsten is combined with carbon in the alloy *Carbaloy*, it forms a very hard material that holds a cutting edge under very severe conditions. Magnesium tungstate is used as a phosphor in fluorescent lamps. Tungsten exhibits valencies of from two to six, but its most stable derivatives are those containing hexavalent tungsten. Some of its better known compounds are WO_3, WF_6, WCl_4, $WOCl_4$, H_2WO_4, $CaWO_4$ and Na_2WO_4. The price is about $6.20 per pound ($13 per kilogram) for the metal of 99.9% purity although material of 98% purity is considerably cheaper.

URANIUM (Named from the planet Uranus). Ger. *Uranium*. Fr. *uranium*. Uranium, a radioactive metal, was discovered in 1789 by M. H. Klaproth in the mineral pitchblende. It was formerly thought to be a member of the chromium series but is now considered to be the fourth element in the actinide series. Uranium has the highest atomic weight of any naturally occurring element. The trans-uranium elements which have higher atomic weights are all synthetics. It occurs as a constituent in several ores such as carnotite, pitchblende and cleveite; the most important deposits being the pitchblende deposits at Great Bear Lake in Canada and the carnotite mines in Colorado and Utah. Good deposits are found in Czechoslovakia and in the Belgian Congo. Being radioactive, it is constantly breaking down, first to uranium X_1, then to uranium X_2, uranium II, ionium, and finally to radium. Radium is, therefore, always associated with uranium, and before the war was the reason behind the treatment of uranium ores, uranium being obtained as a by-product in radium production. Uranium is a lustrous, white metal which tarnishes on exposure to air at room temperature and oxidizes rapidly at temperatures above 200°C., malleable and ductile and capable of taking a high polish. It is not hard enough to scratch glass, and has a density of nearly 19 at 25°C. The metal burns briskly in air at 170°C. to form UO_2. It displaces hydrogen from mineral acids, and displaces mercury, silver, copper, tin, platinum and gold from solutions of their salts. Uranium and its compounds are poisonous to the animal system. Uranium has a valence of six or four. UO_3, UO_2, UCl_6, $UO_2(IO_3)_2$, and UO_2Cl_2 are a few typical uranium compounds. The last two mentioned are *uranyl* compounds. Uranium is sometimes used to harden and strengthen steel, while some uranium compounds are widely employed in ceramics, analytical chemistry and photography. Since the discovery of uranium fission in 1939 uranium has become one of the most important elements. It was found that U-235, an isotope present to the extent of one part in 140 parts of U-238, would undergo nuclear decomposition when bombarded with neutrons. In the enriched piles, the U-235 was first separated from the U-238 (usually by diffusion of the gaseous UF_6) and the two uraniums arranged in a geometrical lattice imbedded in graphite. The reaction is controlled by cadmium strips which can be withdrawn at will. As the chain reaction proceeds, the U-235 emits neutrons which are captured by the U-238 thus forming U-239, each atom of which emits a beta particle becoming neptunium (Np-239). This emits another beta particle and breaks down to plutonium (Pu-239). This is comparatively stable and like U-235 can support a chain reaction but, being a different element, can be separated from uranium by chemical means. Plutonium was produced in large quantities at Hanford, Washington, and was used in the atom bomb. These reactions follow the Einstein law which states that mass can be converted into energy and that one pound equals 11,400,000,000 kilowatt-hours. Since each pound of U-235 breaks down to 0.999 pounds of products, each pound undergoing fission produces 11,400,000 kilowatt-hours of energy. Work is being carried out in efforts to utilize

this energy for peaceful purposes such as the generation of electricity. The price and sale of uranium and its salts are controlled by the U. S. government. The oxide, U_3O_8 is worth about $15 per pound ($33 per kilogram).

VANADIUM (Scand. myth. goddess, *Vanadin*). Ger. *Vanadin*. Fr. *vanadium*. Vanadium is a steel-gray metal capable of taking a very high polish and is the hardest of all metals. It was discovered in 1830 by N. G. Sefstrom in iron ores found near Taberg, Sweden. It does not occur free in nature but is quite common in the combined form, being more abundant than zinc, nickel, nitrogen, or copper. The metal occurs in sufficient concentration to be extracted commercially in several different forms. It has been obtained commercially from the ash of oil burning furnaces. It is usually associated with other ores such as titaniferous magnetites, gold tellurides, and in patronite found in Peru. The United States is the best source of vanadium followed by Africa and Peru. The extraction varies with the type of ore used but the separation is usually a chemical one. It is very difficult to obtain the metal pure but fairly easy to make alloys such as ferrovanadium and nickelvanadium. Vanadium is used, frequently with chromium, in the making of special alloy steels, its presence increasing the toughness of the alloy and adding to the resistance to shock. The metal is also used as a contact catalyst in the manufacture of SO_3, as a reducing agent, as a dryer for linseed oil paints, and as a photographic developer and sensitizer. Vanadium compounds are poisonous when taken internally. Vanadium has valencies of from two to five, and forms four oxides, VO, V_2O_3, VO_2, and V_2O_5. Other common vanadium compounds are V_2S_5, $VOCl_3$, VCl_3, and NH_4VO_3. Ferrovanadium having a 45 to 55% vanadium content sells for about $3 per pound ($6.60 per kilogram) of contained vanadium.

XENON (Gr. *xenos*, a stranger). Ger. *xenon*. Fr. *xénon*. Xenon is a rare, inert, atmospheric gas. It was isolated in 1898 by W. Ramsay and M. W. Travers by distilling liquid argon which also contained the other inert gases. Xenon is the rarest atmospheric gas. It is the least volatile constituent in liquid air and is one of the heaviest gases known. One liter of xenon weighs 5.842 grams, and its vapor density is 65 compared to oxygen as 16. Liquid xenon at −109°C. has a specific gravity of 3.06. Like the other elements in the zero group, it forms no compounds. The gas is seldom prepared pure. The cost of a liter of xenon in glass at normal pressure is about $55.

YTTERBIUM (From *Ytterby*, a town in Sweden). Ger. *Ytterbium*. Fr. *ytterbium*. Ytterbium is a rare earth metal which has not been isolated. It was discovered in 1905 by G. Urbain as a constituent of Marignac's ytterbium which was found to contain two elements that were called lutecium and neo-ytterbium. The latter name has since been shortened to ytterbium. It is found in very small amounts in minerals which contain other rare earths, particularly yttrium. These minerals include gadolinite, polycrase, blomstrandine and others. A few ytterbium compounds are known among them being Yb_2O_3 or ytterbia, and $Yb_2(SO_4)_3 \cdot 8H_2O$.

YTTRIUM (From *Ytterby*, a town in Sweden). Ger. *Yttrium*. Fr. *yttrium*. Yttrium, a metal of the rare earth group, has not yet been prepared in massive form but has been isolated as a gray, metallic powder. It was first separated in the form of yttria by Mosander in 1843, and was named by Ekeberg. It has the lowest molecular weight of the rare earths and, being Element 39, is sometimes considered "out of place" in the periodic table, the other rare earths being numbers 57 to 71 inclusive. Yttrium is one of the most abundant of the rare earths. It is found in company with the other rare earths in monazite sand, gadolinite, blomstrandine, samarskite, xenotime, euxenite and polycrase. The

salts of yttrium are colorless. Y_2O_3, or yttria, YCl_3, $Y(OH)_3$, $Y_2(SO_4)_3$, $Y(NO_3)_3 \cdot 6H_2O$ and others have been prepared. There is a small demand for yttria in the manufacture of Nernst lamps.

ZINC (Ger. *Zink*, akin to *Zinn*, tin). Ger. *Zink*. Fr. *zinc*. Zinc is a bluish-white metal which when pure is malleable and ductile at ordinary temperatures. Commercial zinc must be heated to certain temperatures before it can be worked. Zinc and its compounds have been known since the middle ages especially in India and China. It has had dozens of different names, one of them, *speller*, being applied today to commercial zinc. Paracelsus, an alchemist of about 1570, seems to have been the first to call it "zinckum." Zinc is never found native, its chief ore being sphalerite or ZnS. It is also found as the oxide, zincite, and the carbonate, smithsonite. The metal is generally prepared by roasting the ore and then reducing it with carbon in a distillation furnace above 907°C., the boiling point of zinc. It is many more times abundant than cadmium with which it is nearly always associated. It is widely used in making galvanized iron, which is sheet iron covered with a thin film of zinc. Another important use is as the negative plate in the so-called dry cells. The metal is also used as a precipitant in the cyanide process of refining gold and silver. Impure zinc generally contaminated with arsenic is often used to prepare hydrogen in the laboratory. Large amounts of zinc are used annually in making brass and other alloys. In the pure form it is widely used as a reducing agent in analytical chemistry. Precipitated zinc sulfide is the only white sulfide. This sulfide, suitably prepared and activated, is used in radar and television phosphors. Other zinc compounds, including the silicate, are used in fluorescent lamps. Zinc chloride is one of the commonest soft soldering fluxes. Zinc has a valence of two, forming compounds like ZnO, ZnS, $ZnSO_4$, $ZnCl_2$, and $Zn(NO_3)_2$, as well as the zincates like Na_2ZnO_2, and K_2ZnO_2. The wholesale price of zinc is about 10¢ per pound (22¢ per kilogram).

ZIRCONIUM (Arabian *Zerk*, a precious stone). Ger. *Zirkonium*. Fr. *zirconium*. Zirconium is a silvery white ductile metal which takes a high luster. The bluish-black powdered form is very finely divided material and is usually contaminated with several percent of oxide and other impurities. The oxide was discovered in 1789 by M. H. Klaproth and the metal was first isolated by J. J. Berzelius in 1824. Zirconium does not occur free in nature, being commonly found as the silicate or oxide. It is widely distributed and is more common than copper, lead, nickel or zinc. Large workable deposits exist in Florida, California, Oregon, Iowa and in addition workable deposits occur in Australia, Brazil, India, Ceylon and Malaya. Two unique properties of zirconium affect its extraction, fabrication and utilization; viz., a marked affinity for oxygen and nitrogen forming very stable compounds, and high transparency for thermal neutrons. Of all new structural metals developed as a result of atomic energy requirements none has paralleled the expansion of zirconium either in its production, application or technology. In 1945 the entire U. S. production amounted to only 20 pounds per year and it retailed for about $300 per pound. At present several hundred thousands of pounds are produced at a cost of less than $15 per pound. The metal is prepared as a powder by reduction of the oxide, fluoride, or chloride with the alkali or alkaline earth metals. It can also be prepared by the action of sodium on K_2ZrF_6. Most of the commercially produced metal is made by the Kroll process by the reaction of zirconium tetrachloride with liquid magnesium in an atmosphere of helium yielding a more or less massive sponge. Solid metal is obtained from sponge or powder by pressing and heat-treating compacts in vacuo. The crystalline metal is stable in air and has a bright, silvery luster. Cold workable wire and sheet are produced by the thermal decomposition of zirconium oxide on a heated wire. In the powder form zirconium has a low ignition temperature and it is very explosive when mixed with oxidizing agents. It is employed in this manner in photoflash primers, flares and blasting caps. Zirconium is used in the electronic industries because of its superior "gettering" properties. It has been used as a scavenger in steel and as an alloying element with

steel, copper and nickel. Having low neutron absorption and good resistance to corrosion, zirconium is of interest as a material of construction in atomic energy work. For this purpose it must be freed from the hafnium with which it is nearly always associated. The oxide has been used to replace lime in carbide lamps, to make highly refractory ware such as crucibles and muffles, and as an opacifying agent in glazes. The silicate, zircon, because of its hardness has been used in the knife-edges and planes of analytical balances; in powdered form it is used in making white basing cements for certain incandescent lamps. Zirconium has a valence of four in all of its compounds. ZrO_2, ZrF_4, ZrS_2, $ZrCl_4$ and H_2ZrO_3 are some typical compounds. The price of the crude powdered metal is about $10 per pound ($22 per kilogram); in the form of plate or rod the price is $25 to $30 per pound. However, powdered zircon, $ZrSiO_4$, can be purchased for as little as 5¢ per pound (11¢ per kilogram).

SYNONYMS OF THE ELEMENTS

Alabamine—astatine.
Aldebaranium—ytterbium.
Argentum—silver.
Aurum—gold.
Austrium—impure gallium.
Cassiopeium—lutetium.
Celtium—lutetium.
Columbium—niobium.
Cyclonium—promethium.
Demonium—dysprosium.
Didymium—neodymium+praseodimium.
Dwi-manganese—rhenium.
Eka-aluminum—gallium.
Eka-boron—scandium.
Eka-cesium—francium.
Eka-iodine—astatine.
Eka-manganese—technetium.
Eka-silicon—germanium.
Eka-tantalum—protactinium.
Erythronium—vanadium.
Ferrum—iron.
Florentium—promethium.
Glucin(i)um—beryllium.
Hydrargyrum—mercury.
Ilinium—promethium.
Kalium—potassium.
Masurium—technetium.
Natrium—sodium.
Neoytterbium—ytterbium.
Niton—radon.
Plumbum—lead.
Quicksilver—mercury.
Radium emanation—radon.
Stannum—tin.
Stibium—antimony.
Virginium—francium.
Wolfram(ium)—tungsten.

ABUNDANCE OF THE ELEMENTS

COSMIC ABUNDANCE

The following table lists the relative abundance, expressed in atoms per 10,000 atoms of silicon, of the most abundant elements composing the galaxy of which our solar system is a part. *Chem. & Eng. News*, 30, 1622 (1952).

H	3.5×10^8	Ne	40,000	Ar	130
He	3.5×10^7	Na	462	K	69
C	80,000	Mg	8,870	Ca	670
N	160,000	S	3,500	Fe	18,300
O	220,000	Cl	170	Ni	1,340

TERRESTRIAL ABUNDANCE

Weight of Short-Lived Isotopes Naturally Occurring in the Outermost Mile of the Earth's Land Area *J. Chem. Ed.*, 30, 616 (1953).

Element	Most frequently occurring nuclide	Total mass, grams
Polonium	84 Po-210	4.00×10^9
Astatine	85 At-218	6.86×10^{-2}
Radon	85 Rn-222	1.15×10^8
Francium	87 Fr-223	2.45×10
Radium	88 Ra-226	1.82×10^{13}
Actinium	89 Ac-227	1.13×10^{10}
Protactinium	91 Pa-231	1.69×10^{13}

EFFECTIVE RADII OF ATOMS AND IONS

The values are given in angstrom units. The atomic radii values are from Neuberger, *Zeit. Krist.*, **93**, 1 (1936). To give some idea of the degree of accuracy with which values of ionic radii are known, three sets of values are given; viz., *G*, empirical data from crystal structure by Goldschmidt, *Ber.*, **60**, 1263 (1927); and calculated values *P* and *Z* by Pauling, *J. Am. Chem. Soc.*, **49**, 765 (1927), and Zachariasen, *Zeit. Krist.*, **80**, 137 (1931); cf. also Wherry, *Am. Mineral.*, **14**, 54 (1929).

IONIZATION POTENTIALS OF ELEMENTS

A gaseous ionization potential measures the amount of energy that is needed to remove an electron completely from an atom. In the following table the ionization potential for the elements in the atomic state is expressed in volts and doubtful values are followed by a question mark (?). The degree of ionization is indicated by Roman numerals in the column headings.

Cf., International Critical Tables, vol. 6, p. 69, McGraw-Hill, New York (1929); Sherman, *Chem. Rev.*, **11**, *138 (1932)*; Herzberg, "*Atomic Spectra and Atomic Structures*," pp. 200–1, Prentice-Hall, New York (1937); Slater, "*Introduction to Chemical Physics*," p. 348, McGraw-Hill, New York (1939); Bureau of Standards, "*Atomic Energy Levels*," *Cir.* **467**, vol. 1, table 23, p. XL (1948).

TABLE OF NUCLIDES

The information in this table was prepared by Dr. John R. Stehn and Eugene F. Clancy of the Knolls Atomic Power Laboratory in the course of making the 1956 revision of the General Electric Company's *CHART OF THE NUCLIDES*. These data were made available for use in this *HANDBOOK OF CHEMISTRY* through the co-operation of Dr. James Stokley, News Bureau, General Electric Co., Schenectady, N. Y.

COLUMN HEADINGS

At. No. The *atomic number* gives the number of protons in the nucleus, a value often indicated by the symbol Z.

Mass No. The *mass number* gives the sum of the number of protons and neutrons in the nucleus, a value often indicated by the symbol A.

For any nuclide, the number of neutrons is equal to the difference between the mass number and the atomic number; i.e., $A-Z$. Nuclides with the same mass number are called *isobars;* e.g., calcium-40 (with 20 protons and 20 neutrons) has the same mass number as argon-40 (which has 18 protons and 22 neutrons).

Nuclides with the same atomic number and the same mass number are called *isomers*. For example, there are two nuclides denoted by Scandium-44; these correspond to two different energy states of nuclei containing 21 protons and 23 neutrons. The higher energy isomer is listed first, and the symbol m is attached to its mass number to denote its being in a "metastable" state. A metastable isomer may decay to a lower energy isomer, emitting energy via gamma radiation or internal conversion electrons; this type of decay is called an "isomeric transition" (*IT*).

Mass. For the various nuclides the mass value is based on the *physical* scale of atomic weights (*psaw*) where the mass of O^{16} equals 16 exactly. For the chemical elements the 1955 International Atomic Weights are given and these are based on the *chemical* scale of atomic weights (*csaw*) where the atomic weight of oxygen in its naturally occuring state equals 16 exactly. The values for these atomic weights of the elements are enclosed in parentheses.

Abundance in %. Here are given the percentages of stable nuclides present in naturally occuring elements. These values are expressed in percentages by numbers of atoms, not by weight.

Half-Life. For radioactive elements, this is the period of time required for half of the nuclei to undergo disintegration.

Radiation Decay. Data in this column show first the principal mode of decay (including the energy of the initially produced radiation), followed first by the less frequent modes of decay, and then by the subsequent radiations and their energies. All energies are expressed in units of million electron volts (Mev). The letter *D* after a gamma energy indicates that that particular radiation is delayed by a measurable amount (but less than a millisecond). When a radiation is emitted by a short-lived daughter of a longer-lived parent nuclide, this radiation has in effect the same half-life as the parent nuclide. In this case the radiation is enclosed in parentheses with the parent's radiations to indicate its origin.

Cross-Section. The ability of a nuclide to absorb thermal neutrons and transmute itself into another nuclide is given here in units of 10^{-24} cm^2 (a *barn*). The usual product of the transmutation is a nuclide of the next higher mass number; the cross-section for such transmutation is denoted by σ. If there are two nuclides of the next higher mass number (isomers), two cross-sections may be tabulated, the first leading to the isomer tabulated on the next line, whose designation is suffixed by an m. If only one cross-section is tabulated, this is the sum of the two separate ones. For a few light nuclides, transmutation by the (n,p) reaction (neutron in, proton out) is possible; when its cross-section is known, it is denoted by σnp. For a few heavy nuclides, thermal fission occurs, with a cross-section denoted by σF.

Disintegration Energy. This value, given in the column headed E, is the total energy change (in Mev) involved in a radioactive beta disintegration, the sum of beta, neutrino, gamma, and conversion electron energies.

TABLE OF NUCLIDES

Abbreviations and symbols used in the table

TIME

s	second
m	minute
h	hour
d	day
y	year

RADIATION DECAY

Modes of Decay

α	alpha particle
β^-	negative beta particle
β^+	positive beta particle
K	K-electron capture
L	L-electron capture
IT	isomeric transition
n	neutron (or neutron emission)
p	proton (or proton emission)
SF	spontaneous fission

Subsequent Radiations

γ	gamma ray
e^-	prominent internal conversion electron
(n)	"delayed" neutron
(α)	"delayed" alpha particle
(β)	"delayed" beta particle

* a nuclide known to be a fission product of U^{235} after fission by thermal neutrons

CROSS-SECTION

σ (for nuclides): for (n, γ) reaction (neutron capture)
σ (for elements): for all neutron-absorbing reactions
σnp: for (n,p) reactions σF: for fission

NUCLIDE COMPOSITION OF THE EARTH'S ATMOSPHERE

I. Asimov, *J. Chem. Ed.* **32**, 633 (1955).

Based on the assumption that the earth's atmosphere at 0°C and 760 mm Hg pressure is equal to one billion cubic miles; and with a composition of 78.09% N_2, 20.95% O_2, 0.93% Ar, 0.03% CO_2, 18.05 ppm Ne, 5.00 ppm He, 0.99 ppm Kr, 0.09 ppm Xe

(Expressed in parts per billion—by volume.)

$N^{14}N^{14}$	7753×10^5	He^4	50×10^2	Xe^{129}	23
$O^{16}O^{16}$	2085×10^5	Ne^{22}	17×10^2	Kr^{80}	20
A^{40} or Ar^{40}	926×10^4	$O^{18}O^{18}$	830	Xe^{131}	19
$N^{14}N^{15}$	560×10^4	Kr^{84}	560	Xe^{134}	9
$O^{16}O^{18}$	80×10^4	$O^{17}O^{18}$	340	Xe^{136}	8
$C^{12}O^{16}O^{16}$	30×10^4	Kr^{86}	170	Xe^{130}	3
$O^{16}O^{17}$	16×10^4	Kr^{82}	120	Kr^{78}	3
A^{36} or Ar^{36}	32×10^3	Kr^{83}	120	Xe^{128}	18×10^{-1}
Ne^{20}	163×10^2	Ne^{21}	50	Xe^{124}	9×10^{-2}
$N^{15}N^{15}$	112×10^2	$O^{17}O^{17}$	30	Xe^{126}	6×10^{-2}
A^{38} or Ar^{38}	56×10^2	Xe^{132}	24	He^3	6×10^{-3}

PROPERTIES OF MINERALS

Compiled by **Clarence E. Miller,** *M. Sc.*

Synonyms:

At the bottom of each page are alternate names for minerals to be found in the main body of the table but listed there under a different name. The number following the name refers to the numerical place in the table for the same substance; thus, *Acmite* 554 indicates that this mineral is the 554th mineral in the table where it will be found listed under the *pyroxene* group. The names at the bottom of the page include also the names of varieties and these are indicated by the abbreviation *var.* or by the letter *v* following the number; also included are the names of minerals for which complete data are lacking as well as names for those substances not well established as mineral species.

Mohs' Scale of Hardness:

1, talc; 2, gypsum; 3, calcite; 4, fluorite; 5, apatite; 6, orthoclase; 7, quartz; 8, topaz; 9, corundum, 10, diamond.

"Working Scale of Hardness:"

1, very easily scratched by finger nail, and have greasy feel to the hand; 2, easily scratched by finger nail; 3, scratched by brass pin or copper coin; 4, easily scratched by knife; 5, scratched with difficulty with knife; 6, easily scratched by file; 7, are but little touched by file, but will scratch window glass. All harder than 7 will scratch window glass.

Abbreviations

In compiling the data in Table of Minerals, the following abbreviations have been used:

—*under* Name:

Ra., radioactive; ?, questioned or doubtful.

—*under* Crystal System:

C, Isometric; Tet., tetragonal; H, hexagonal; R, orthorhombic; M, monoclinic; Tri., triclinic; Am., amorphous; Crypt., cryptocrystalline; iso., isotropic; ?, doubtful.

—*under* Index of Refraction:

All values, unless noted, are those of the mean value or β; η, index of refraction for all isotropic minerals, and when used with biaxial or uniaxial minerals denotes that no definite directional value has been determined; ω is the index of refraction value for the ordinary ray and is used in giving the index of uniaxial minerals; α and γ, where used denote, respectively the values of minimum and maximum indices of refraction of biaxial minerals; ϵ is used to denote the value of index of the extraordinary ray in uniaxial minerals.

—*under* Color:

W, white; R, red; Reds, various shades of red; Bl., blue; Blk., black; Br., brown; O, orange; Y, yellow; Grn., green; Greens, various shades of green; Gr., gray; V, violet; Pr., purple; Pk., pink;—or colorl., colorless; d, deep shade; all of the abbreviations above when in lower case type (as grn. for greenish) indicate the ending of the word with "ish."

TABLE A

No.	Name	Composition	Crystal System	Hardness	Specific Gravity	Refractive Index	Color

SHORT, M. N., **Microscopic Determination of the Ore Minerals.** U. S. Geolog. Surv. Bul. 914, 1940; Washington.
The American Mineralogist. Vols. 1 to 36 (1951). Published by the Mineralogical Society of America.
Mineralogical Magazine and Abstracts. Magazine 1876 to 1949; Abstracts 1920 to 1949. Published by the British Mineralogical Society; London.
GEORGE, R. D., **Minerals and Rocks.** 1943. Published by D. Appleton-Century Company, New York.

Von Kobell's Scale of Fusibility:
1, stibnite; 2, natrolite, 3, garnet, lime-alumina variety; 4, hornblende; 5, orthoclase; 6, bronzite; 7, infusible.
Penfield's Scale of Fusibility:
1, stibnite, fuses readily in candle flame; 2, chalcopyrite, fuses in the luminous flame, but with difficulty in closed tube; 3, almandite, fuses readily in the blowpipe; 4, actinolite, edges are readily rounded in the blowpipe flame; 5, edges are fused with difficulty in the blowpipe flame; 6, bronzite, only the thinnest splinters are rounded by fusion in the blowpipe flame; 7, infusible.

—*under* Luster:
M, metallic; V, vitreous; A, adamantine; G, greasy; W, waxy; R, resinous; D, dull; E, earthy; Pl., pearly; Sk., silky; Sn., satiny; Sp., splendent; s, sub.

—*under* Fusibility:
Numbers 1, 2, 3,... 6 degrees of fusibility; see **Scale of Fusibility**, if, infusible; f, fusible; df., difficulty fusible; ef., easily fusible; vol., volatile.

—*under* Solubility:
i., insoluble; s., soluble; sl., slightly or partly; dec., decomposes or decomposed; aq. reg., aqua regia; gel., gelatinizes; turp., turpentine; alc., alcohol; a., acid.

—*under* Special Properties:
Photoluminescence includes phosphorescence or fluorescence caused by X-ray, or ultra violet light, or argon lamp, abbreviated (A), or exposure to radium (R).
Cer., cerium metals; Yttr., yttrium metals; E, rare earths; mole/unit cell, moles per unit cell; B. B., before blow pipe; pH, abrasion pH, the value obtained by grinding the mineral in a few drops of water and determining the pH of the liquid with prepared indicator test papers.

—*under* Localities:
Only the important localities of fine specimens, or crystallized material is given in case of the more common minerals.
A., abundant; C., common; Unc., uncommon; R., rare; V.R., very rare.

CLAY MINERALS

A clay mineral is a hydrous aluminum silicate, variable in chemical and physical properties, whose two- or three-layer crystal lattice permits the replacement of aluminous ions by non-aluminous ions to form non-aluminous clays. Exchangeable cations may be on the surface of the silicate layers and their amounts are determined by their excess negative charge within the layer. These cations are usually Ca and Na, but K, Mg, H, and Al may also be exchangeable. Members of the kaolinite, montmorillonite and illite groups are the most common of the clay minerals. In the following list, the clay minerals are listed according to the accepted clay mineral grouping or classification.

For more complete data see: R. E. Grim, Properties of Clays, Recent Marine Sediments, *Am. Assoc. Pet. Geol.* (1939), Tulsa, Okla.; R. E. Grim, Modern Concepts of Clay Minerals, *J. Geol.*, **50**, 225 (1942); P. F. Kerr et al., *Am. Petroleum Inst. Project* **49**, preliminary reports Nos. 1–7, Clay Mineral Standards.

BAUXITE GROUP

This group consists of those oxides of aluminum, either hydrous or colloidal, and secondary in origin, resulting from the decomposition of various minerals through weathering, leaching, or by the action of volcanic gas. Kaolins may be formed from them by silicification.

Alumogel, cf. cliachite

Bauxite: a colloidal mixture of varying proportions of the minerals gibbsite, boehmite, diaspore, cliachite, and sporogelite.

Boehmite: crystalline (?) $Al_2O_3 \cdot H_2O$.

Cliachite: amorphous $Al_2O_3 \cdot H_2O$.

Diaspore: crystalline, orthorhombic $Al_2O_3 \cdot H_2O$.

Diasporogelite, cf. cliachite.

Gibbsite: finely crystalline, monoclinic $Al_2O_3 \cdot H_2O$.

Hydrargillite, cf. gibbsite.

α-Kliachite: colloidal $Al_2O_3 \cdot H_2O$.

β-Kliachite: colloidal $Al_2O_3 \cdot H_2O$.

Sporogelite: colloidal $Al_2O_3 \cdot H_2O$.

HALLOYSITE GROUP

A group of porcelain-like clay minerals of the general formula $Al_2Si_2O_5(OH)_4$ which, under the electron microscope, show crystallinity in the form of minute, slender, *hollow tubes*. On dehydration these tubes may split and "unroll." They may also form tube-within-tube arrangements.

Allophane: the amorphous material associated with halloysite.

Endellite: a more hydrous halloysite, $Al_4Si_4O_{10}(OH)_8 \cdot 4H_2O$.

Halloysite: a general term for a group of related minerals; cf. group definition.

Hydrated halloysite, cf. endellite.

Hydrohalloysite, cf. endellite.

Indianite: a white porcelain-like mixture of halloysite and kaolinite.

Metahalloysite: a dehydrated form of halloysite, $Al_4Si_4O_{10}(OH)_8 \cdot 2H_2O$.

Schrötterite: a mixture in which the glassy mineral is halloysite and the earthy mineral is variscite.

ILLITE GROUP

A group related to the micas and of a complex chemical composition with the general formula $(OH)_4K_y(Al_4 \cdot Fe_4 \cdot Mg_4 \cdot Mg_6)(Si_{8-y} \cdot Al_y)O_{20}$. This group embraces the most common and widespread of the clay minerals and is the chief constituent of clay minerals and shales.

Brammallite: a soda-rich illite.

Bravaisite: a mixture of illite and montmorillonite with illite in excess.

Glimmerton, cf. illite.

Hydromica: a commonly occurring, micaceous clay mineral resembling sericite.

Illite: a general term for a group of mica-like minerals so common in argillaceous sediments; not a specific mineral species; cf. group definition.

CLAY MINERALS

Sericite: a silky, mica-like mineral similar to, although not a variety of, muscovite and of supergene and hypogene origin; unstable in acidic solutions; a hydrous K, Al silicate.

KAOLINITE GROUP

A group of hydrous aluminum silicates which are the chief constituents of the white clay *kaolin*.

Anauxite: the high silica member of the kaolinite group with the formula $Al_2O_3 \cdot 3SiO_2 \cdot 2H_2O$.

Carnat, cf. kaolinite.

Clayite: a name proposed, but now discredited, for a colloidal kaolinite.

Collyrite: a mixture of kaolinite and halloysite.

Dickite: a hydrothermally formed substance not commonly found in sediments and with a composition similar to kaolinite.

Ferrikaolinite: the hypothetical substance $H_4Fe_2Si_2O_8$.

Ionite, cf. anauxite.

Kaolin: a white burning clay; cf. kaolinite.

Kaolinite: the characteristic mineral of kaolin with the formula $Al_2O_3 \cdot 2SiO_2 \cdot 2H_2O$.

Marge porcellana: a mixture of kaolinite and halloysite.

Metakaolinite: artificially dehydrated kaolin.

Metanacrite: artificially dehydrated nacrite.

Microvermiculite, cf. kaolinite.

Nacrite: a hydrothermally formed substance rarely found in sediments and chemically the same as kaolinite but differing in physical properties; in the direction of the c-axis, it is the most closely stacked followed in decreasing order of close-stacking by dickite and then kaolinite.

Neokaolin: a kaolin artificially formed from nepheline.

Pholerite, cf. kaolin.

Prokaolin: an assumed amorphous weathering product which passes progressively into kaolinite.

Rectorite, cf. kaolinite.

Severite: a mixture of kaolinite and halloysite.

Terra porcellana: a mixture of kaolinite and halloysite.

Terra samia, cf. kaolin.

MONTMORILLONITE GROUP

A group of complex clays of the three-layer crystal lattice type, named after the chief member of the group. With beidellite and nontronite as end members this group of minerals forms a continuous series of solid solutions with Fe(III) and Al proxying for one another in all proportions in the lattice structure. Aluminum also proxies for Si not exceeding one ion in four.

Amargosite: a trade name for a bentonite clay from the Amargosa River in California.

Beidellite: the aluminum end member of the montmorillonite-nontronite series with the formula $Al_{2.17}(Al_{0.83}Si_{3.17})O_{10}(OH)_2Na_{0.33}$.

Bentonite: a rock composed essentially of mixtures of montmorillonite and beidellite with the former predominating; also a trade name given to highly adsorptive clays or "swelling" drilling muds.

Chloropal, cf. montronite.

Erinite: a montmorillonite from Ireland.

Ferromontmorillonite, cf. nontronite.

Hectorite: the magnesium end member of the montmorillonite group found in Hector, California. The lithium is an essential part of its formula $(Mg_{2.67}Li_{0.33}) \cdot Si_4O_{10}(OH)_2Na_{0.33}$. It absorbs water with a great increase in its volume.

Magnesium beidellite, cf. hectorite.

Metabentonite: a potash-bearing Ordovician clay which is a mixture of alternating layers of illite and montmorillonite with illite predominating.

CLAY MINERALS

Montmorillonite: a clay mineral from Montmorillon, France (1847). It is the essential mineral in clay rock bentonite, a common mineral in the soils as well as in association with mineral deposits. It is a complex hydrous magnesium aluminum silicate with essential sodium and calcium and having, according to Ross and Hendricks, the formula $5Al_2O_3 \cdot 2MgO \cdot 24SiO_2 \cdot 6H_2O \cdot (Na_2O, CaO)$.

Nontronite: the iron end member of the montmorillonite group with the formula $Fe(III)_{2.00}(Al_{0.67}Si_{3.67})O_{10}(OH)_2Na_{0.33}$.

Otaylite: a magnesium bentonite clay found in Otay, California; also a trade name for this clay.

Piotin: a discredited name for saponite.

Saponite: a high magnesium member of the montmorillonite group of hydrothermal origin and with the formula $Mg_{3.00}(Al_{0.33}Si_{3.67})O_{10}(OH)_2Na_{0.33}$.

Smectite: the original name for clays of the montmorillonite type which present day usage advocates dropping; at one time the name was used synonymously for fuller's earth.

PALYGORSKITE GROUP

A group, incompletely studied, which includes members of the sepiolite-attapulgite isomorphous series with sepiolite as one end member and the hypothetical paramorillonite as the other. Lapparent (1935) believes this group to be mixtures of kaolinite and sepiolite.

Attapulgite: the chief mineral in the fuller's earths from Florida and Georgia, U. S. A. An extensive replacement of Al for Mg is possible in its formula $5MgO \cdot 8SiO_2 \cdot 9H_2O$. It is a good material for decolorizing oil.

Calciopalygorskite: the name proposed for the calcium-rich member of the palygorskite group.

Floridin-Floridine: a trade name for the fuller's earth supplied by the Floridin Company of Quincy, Florida.

Gumbrine: a fuller's earth from Kutais Georgia, Transcaucasia.

Lasallite, cf. α-palygorskite.

Meerschaum, cf. Table of Minerals.

Palygorskite: a specific name for minerals of the palygorskite group which have aluminum substituting for magnesium. Grim (1942) questions its existence.

α-Palygorskite: a fibrous, hydrous aluminosilicate of magnesium and composed of one molecule of parasepiolite with two molecules of paramontmorillonite.

β-Palygorskite: a mineral containing one molecule each of parasepiolite and paramontmorillonite.

Paramontmorillonite: the hypothetical aluminum end member of the palygorskite group and with the formula $Al_2O_3 \cdot 5SiO_2 \cdot 6H_2O$. Kerr (1937) notes that no known mineral corresponds to this.

Parasepiolite: the fibrous or alpha variety of sepiolite and with the formula $2MgO \cdot 3SiO_2 \cdot 4H_2O$.

Sepiolite: the magnesium end member of the palygorskite group and with the formula $2MgO \cdot 3SiO_2 \cdot 2H_2O$.

UNCLASSIFIED GROUP

Allophanoids: a term used to indicate allophane, halloysite and montmorillonite clays.

Bole: a medical term for clays used in ancient medicines.

Catlinite: a name, but not a mineral species, for red clay used by the North American Indians in the making of their smoking pipes.

Cimolite: a fuller's earth; a mixture with some alunite.

Collophane: the principal mineral of phosphate deposits; although not a clay mineral it is frequently a constituent of sediments.

Damourite: a variety of muscovite.

Drilling mud: any of the bentonites, weighted with barite or hematite, used to seal or "mud off" excess water or gas and to catch and carry up the drillings from rotary drills in the drilling for petroleum.

CLAY MINERALS

Evansite: a hydrous aluminum phosphate; cf. allophane.
Faratsihite: a mixture of kaolinite and nontronite.
Fuller's earth: any clay which has a high natural adsorptive capacity; it may be a member of either the montmorillonite or palygorskite groups.
Glacialite: a trade name for a white clay from Enid, Oklahoma.
Glauconite: essentially a hydrous iron and potassium silicate found in marine deposits of every geological age.
Grundite: a trade name for a non-bentonitic clay allied to illite and coming from Grundy County, Illinois; it is used as a fuller's earth and a drilling mud.
Gummite: a discredited name formerly applied to a "gum-like halloysite" and now used for the alteration product of uraninite.
Leverrierite: a mixture of muscovite and kaolinite.
Lithomarge: a mixture of kaolinite and halloysite.
Miloschite: a chromiferous kaolinite and/or halloysite; not a definite species.
Parakaolinite: the end member of the serpentine-parakaolinite series with the formula $1.01Al_2O_3 \cdot 2SiO_2 \cdot 2.09H_2O$.
Phyllite: a rock name for fine grained schists; it should not be used as a general term for scaly minerals, micas, chlorites and clays as has been done by some French authors.
Porcellana: a mixture of kaolinite and halloysite.
Potash bentonite: a name applied to the potash-bearing clay mineral of altered volcanic ash; cf. metabentonite.
Potash montmorillonite: a high potash (4.60% K_2O) and low water clay mineral of the metabentonites found in Missouri.
Ptilolite: an orthorhombic, zeolite-like clay mineral with the formula $(Ca,K,Na)O \cdot Al_2O_3 \cdot 10SiO_2 \cdot 7H_2O$.
Pyrophyllite: a material resembling talc and with the formula $Al_2O_3 \cdot 4SiO_2 \cdot H_2O$; it is generally considered not to be a clay mineral.
Sericite: a supergene muscovite.
Walkerde: a German term for fuller's earth.
Wilkonite: a highly colloidal bentonitic clay used as a filler in making book paper.

RADIO DETECTOR MINERALS

E. T. Wherry, *Am. Mineralogist*, **10**, *part 2, page 28 (1925)*.

Zincite

HEAVY LIQUIDS FOR MINERALOGICAL ANALYSES

Recommended by Messmore, and Sullivan (*Bu. of Mines, Techn. Paper*, No. 381).

For the laboratory study of ores, only two heavy liquids are usually necessary. Acetylene tetrabromide is recommended for all low gravity work. Many ores contain quartz or calcite as gangue, and acetylene tetrabromide has enough gravity to float free a gangue composed of either of these minerals. As many ores contain more gangue than valuable minerals, the use of acetylene tetrabromide is recommended because it will remove the larger part of the sample; the smaller remaining part may then be treated with a more expensive, heavier liquid.

The most suitable liquid for sink-and-float work on minerals of high specific gravity is a water solution of the double thallous formate-malonate. This double salt, with a specific gravity of 4.9, melts at 60°C. and is miscible in all proportions with water. At room temperatures the salt is sufficiently soluble to give a solution with a specific gravity of nearly 4.3. As a liquid of intermediate gravity, an aqueous solution of thallous formate is recommended. It is less expensive than the formate-malonate. A maximum specific gravity of about 3.5 is reached at room temperatures, and gravities up to 4.95, the gravity of the molten salt, may be obtained.

Because of the cheapness and desirable properties acetylene tetrabromide diluted with carbon tetrachloride is recommended for gravities of 2.95 and below; because of its cheapness compared with the malonate-formate, thallous formate solution is recommended for gravities from 2.95 to 3.5; and the malonate-formate solution is recommended for gravities above 3.5.

Sp. Gr. Range	Heavy Liquid	Diluting and Washing Reagent	Recovery, etc.
Messmore:-			
1.6 to 2.95	acetylene tetrabromide	chloroform or benzene	evapn. or fractional distn.
2.95 to 3.5	thallous formate	water	evapn. on the steam bath
3.5 to 4.9	thallous formate-malonate	water	evapn. on the steam bath
Sullivan:—			
1.58 to 2.6	*bromoform*	carbon tetrachloride	fractional distn.; liquid at room temp.
2.6 to 2.9	acetylene tetrabromide	carbon tetrachloride or benzene	fractional distn.; liquid at room temp.
2.9 to 3.3	stannic bromide ($SnBr_4$)*	carbon tetrachloride	distn.; $SnBr_4$ melts at 31°C. but addition of CCl_4 lowers m.p. to room temp.
3.3 to 3.65	antimony tribromide *stannic bromide**	carbon disulfide, abs. alcohol, bromoform or dry acetone	fractional distn.; melts on the steam bath
3.65 to 4.95	thallous formate	water	evapn. on steam bath; melts on the steam bath
4.95 to 5.2	eutectic of mercuric chloride and mercuric iodide + antimony trichloride	aniline, followed by alcohol or ether	melts on oil bath; cannot be used when sulfides are present

* Decomposed by water: mineral particles must be dry.

SHORT GLOSSARY OF INORGANIC CHEMICAL NOMENCLATURE

The following rules for naming inorganic compounds and the examples given in explanation are not intended to cover all of the possible cases. For a more comprehensive and detailed description see: Definitive Report of the Commission on the Reform of the Nomenclature of Organic Chemistry, *J. Am. Chem. Soc.*, **55**, 3905 (1933); Fernelius, *Chem. Eng. News*, **26**, 161 (1948); *ibid.*, **26**, 520 (1948); Watt, *Science*, **108**, 740 (1948); Scott, *Inorganic Syntheses*, II, 257, McGraw-Hill, New York (1946).

Inorganic compounds are named customarily with the more electropositive (metallic) element mentioned first. This corresponds to the order of elements used in writing the formula; thus, NaCl is *sodium* chloride; $CaSO_4$ is *calcium* sulfate; CO_2 is *carbon* dioxide. For inorganic compounds, comprised of non-metals only, the order of writing the symbols of the elements in the formula and of naming the compound is to write and name the more positive element first. The order, therefore, is Sb, As, B, Si, C, P, Te, Se, S, I, Br, Cl, F, N, O. It is to be noted, however, that an exception is in the cases of compounds of nitrogen with halogens. In these cases nitrogen comes first in writing the formulas and the corresponding names; thus, NCl_3 is nitrogen trichloride.

Binary compounds (i.e., compounds of two elements) are named with the suffix *-ide;* thus, BN is boron nitr*ide;* SiC, silicon carb*ide;* PbS, lead sulf*ide;* Al_2O_3, aluminum ox*ide*.

Compounds of hydrogen with the more electropositive elements, ionic and interstitial types, are designated as *hydrides* (e.g., NaH is sodium hydride), but the volatile covalent compounds of hydrogen with the more electronegative elements are named according to the rules for binary compounds or as *acids* (see below); thus, PH_3 is known as hydrogen phosphide or hydrophosphoric acid, and also as phosphine, its trivial name; H_2S is hydrogen sulfide or hydrosulfuric acid.

Where more than one compound of the same two elements exists, confusion in naming the compounds is avoided by the following rules. In the case of binary compounds of metals and non-metals, the suffix *-ic* is given to the name of the metal in its higher state of oxidation (higher valence); the suffix *-ous* is used for the metal in its lower state of oxidation; thus, Fe_2O_3 is ferr*ic* oxide, FeO is ferr*ous* oxide; $CuCl_2$ is cupr*ic* chloride, CuCl is cupr*ous* chloride; SnS_2 is stann*ic* sulfide, SnS is stann*ous* sulfide. A numerical prefix* to the name of the second element in the formula of a compound is used also to distinguish between several different compounds of the same pair of elements. This method is employed especially in the case of binary compounds of two non-metals; thus, P_2O_3 is phosphorus *trio*xide; P_2O_5 is phosphorus *penta*oxide; CO is carbon *mon*oxide; CO_2 is carbon *di*oxide. The state of oxidation (valence) may be shown also by writing a Roman numeral in parentheses following the element to which it refers; thus, the name *tin (IV) chloride* may be used in place of stannic chloride for $SnCl_4$ to indicate that the element tin in this chloride has a valence of four; similarly, the name *tin (II) chloride* may be used in place of stannous chloride for $SnCl_2$.

Covalent compounds containing two or more simple electronegative (non-metallic) elements are named in alphabetical order of their electronegative constituents (except that *hydroxy-*, *oxy-*, and *sulfo-* are mentioned first); e.g., PBr_2F is phosphorus (III) dibromofluoride; $PSCl_3$ is phosphorus (V) sulfochloride; $POCl_3$ is phosphorus (V) oxychloride. This system of naming is preferable to that which uses a suffix *-yl* for oxy-radicals except for the names chromyl (CrO_2), carbonyl (CO), thiocarbonyl (CS), sulfuryl (SO_2), thionyl (SO), nitrosyl (NO), nitryl (NO_2); e.g., $SOCl_2$ is *thionyl* chloride whereas $VOCl_3$ is vanadium (V) *oxy*chloride rather than vanad*yl* chloride.

Many compounds containing three or more elements are named as binary compounds because two or more of the elements act much like a single element (radical). The more electropositive element or radical is normally designated by a suffix *-ium* whereas the more electronegative element or radical has the suffix *-ide* appended. Thus, KOH may be considered as composed of potassium (K) and the hydroxyl radical (OH) and is named potassium hydroxide; similarly potassium cyanide (KCN), and sodium amide ($NaNH_2$) are named with the suffix *-ide* since the amide radical (NH_2)

* See special table of numerical prefixes.

and the cyanide radical (CN) act as units. Examples of "onium" compounds are ammonium chloride (NH_4Cl) and phosphonium chloride (PH_4Cl) because in these compounds the ammonium radical (NH_4) and the phosphonium radical (PH_4) act as units.

Binary acids consisting of hydrogen and one other element are named for the characteristic element with the prefix *hydro-* and the suffix *-ic*. For example, HCl is named *hydro*chlor*ic* acid; HBr is named *hydro*brom*ic* acid; HCN is named *hydro*cyan*ic* acid, with the radical (CN) acting as a single element. Salts of these acids are named as binary compounds. Thus, NaCl is named sodium chloride; NaBr is sodium bromide; and NaCN is sodium cyanide.

Ternary acids (i.e., oxy-acids containing oxygen and hydrogen and another element) are named by giving the suffix *-ic* to the name of the characteristic element present. Thus, H_3BO_3 is named bor*ic* acid; H_2SO_4 is named sulfur*ic* acid. When the characteristic element forms two acids corresponding to two states of oxidation (valence), the suffix *-ic* refers to the acid with the characteristic element in a higher state of oxidation (valence) and *-ous* refers to the acid of lower valence for the third element. Thus, in sulfur*ic* acid (H_2SO_4) sulfur has a valence of 6 whereas in sulfur*ous* acid (H_2SO_3) the valence of sulfur is 4; similarly, HNO_3 is nitr*ic* acid and HNO_2 is nitr*ous* acid; H_3AsO_4 is arsen*ic* acid and H_3AsO_3 is arsen*ous* acid. Where more than two oxy-acids of an element exist, the prefix *per-* is added to the name of the acid in the higher state of oxidation along with the *-ic* suffix to denote the acid of the highest state of oxidation. Similarly, the prefix *hypo-* and the suffix *-ous* are used to designate a state of oxidation lower than that of the "*-ous*" acid. The following oxy-acids of chlorine serve as illustrations. The valence of chlorine is shown by a Roman numeral in parentheses in each case. *Per*chlor*ic* acid, $HClO_4$ (VII); chlor*ic* acid, $HClO_3$ (V); chlor*ous* acid, $HClO_2$ (III); *hypo*chlor*ous* acid, HClO (I). However, acids with a prefix *per-* in their names should not be confused with *peroxy* acids in which there is a peroxy linkage (—O—O—) similar to that in hydrogen peroxide. The position of the numerical prefix in these compounds is very important. Thus, H_2SO_5 (H—O—O—SO_2·OH) is *peroxy*monosulfur*ic* acid; $H_2S_2O_8$ (HO·SO_2—O—O—SO_2·OH) is peroxy*disulfur*ic acid; H_2CO_4 (H—O—O—CO·OH) is *monoperoxy*carbonic acid; H_2CO_5 (H—O—O—CO—O—O—H) is *diperoxy*carbonic acid.

Corresponding to an element in a single state of oxidation there may be two or more acids depending on the amount of water combined with the acid *anhydride*. These acids may be known either in the free state or in their salts or esters. In naming such acids the prefix *ortho-* usually refers to the highest hydroxylated acid. The prefixes *pyro-*† and *meta-* refer to successive stages of dehydration. For example, the following three acids contain phosphorus with a valence of 5: *ortho*phosphor*ic* acid, H_3PO_4, containing the maximum amount of water combined with the acid anhydride ($3H_2O·P_2O_5$); *pyro*phosphor*ic* acid, $H_4P_2O_7$ (i.e., $2H_3PO_4 - H_2O$, or $2H_2O·P_2O_5$); and *meta*phosphor*ic* acid, HPO_3 (i.e., $2H_3PO_4 - 2H_2O$, or $H_2O·P_2O_5$).

Salts of the oxy-acids are named with the name of the more electropositive element or radical followed by that of the acid with the suffix *-ate* when the name of the acid has the suffix *-ic;* thus, sodium nitr*ate* ($NaNO_3$) is a salt of nitr*ic* acid. If a salt corresponds to an acid with the suffix *-ous* in its name, the name of the salt ends in *-ite;* thus, sodium nitr*ite* ($NaNO_2$) is a salt of nitr*ous* acid. The prefixes *per-, hypo-, ortho-, pyro-,*† and *meta-* are used in naming salts corresponding to acids with such prefixes in their names; thus, sodium *per*chlor*ate* ($NaClO_4$) is a salt of *per*chlor*ic* acid; sodium *hypo*chlor*ite* (NaClO) is a salt of *hypo*chlor*ous* acid.

When an acid containing two or more replaceable hydrogen atoms in the molecule is partially neutralized, an *acid salt* results. It is recommended that the name of the electropositive element or radical be given first and followed by the word *hydrogen;* thus, $NaHSO_4$ is *sodium hydrogen* sulfate; Na_2HPO_4 is *disodium hydrogen* phosphate (or *disodium hydrogen* orthophosphate); NaH_2PO_4 is *sodium dihydrogen* phosphate; $N_2H_5·HSO_4$ is *hydrazonium hydrogen* sulfate. Similarly, salts of polyhydroxy-metallic hydroxides are named with the word *hydroxy* between the name of the metal and the acid radical; Mg(OH)Cl is magnesium *hydroxy* chloride.

When another element replaces an oxygen atom in the anion of an acid, this is

† A pyro-acid is the same as a poly-acid. Common salts of poly-acids are $Na_2B_4O_7$, sodium tetraborate (trivial name, borax); $K_2Cr_2O_7$, potassium dichromate; many silicates.

designated by using the proper prefix for the substituting element; e.g., $H_2S_2O_3$ is named *thio*sulfuric acid because a sulfur atom (prefix *thio-*) replaces one of the oxygen atoms in sulfuric acid (H_2SO_4). Sodium thiosulfate ($Na_2S_2O_3$) is a salt of this acid. Similarly, when two or more oxygen atoms are replaced, a numerical prefix (see table of *Numerical Prefixes*) is used to designate the number of replacing atoms; e.g., H_2SnCl_6 is named *hexa*chlorostannic acid because six (*hexa*) chlorine atoms have replaced the three oxygen atoms in stannic acid (H_2SnO_3).

In coordination compounds the more positive ion or radical is named first as in the naming of binary compounds. Within the coordination brackets, the negative groups are named first, followed by the neutral and positive groups, respectively. The suffix *-o* is added to the name of the negative group. Thus, the name "bromopentamminecobalt (III) bromide," for the compound $[Co(NH_3)_5Br]Br_2$, is an illustration of the order of naming and the use of the suffix "*-o*." The suffix *-ium* is added to the name of a positive group; the name "diamminedihydrazoniumplatinum (II) chloride," for the compound $[Pt(NH_3)_2(N_2H_5)_2]Cl_4$, illustrates the order of naming within the coordination sphere and the use of the suffix "*-ium*" to designate a positive group (N_2H_5, hydrazonium). No suffix is added to the name of a neutral group in the coordination sphere; for example, the name "tetrapyridineiron (II) chloride," for the compound $[Fe(C_5H_5N)_4]Cl_2$. In this example the neutral group (pyridine) is in the coordination sphere and no suffix is appended to its name.

In case several groups of like polarity are present an alphabetical order is used; e.g., in the compound $[Co(OH)(C_2O_4)(NH_3)_3]$ both the hydroxo (OH) and the oxalato (C_2O_4) are negative groups, consequently they are listed alphabetically in the name hydroxooxalatotriamminecobalt (III)"; in the compound $[PtCl(NO_2)(NH_3)(C_5H_5N)]$ there are two negative groups and two neutral groups in the coordination sphere, consequently, an alphabetical listing is used for each type, with the negative type being listed first, and the compound is named "chloronitroamminepyridineplatinum (II)." Due to well established usage, coordinated ammonia is designated as *ammine* and coordinated water as *aquo;* e.g., $[Zn(NH_3)_6]Cl_2$ is named "hexamminezinc (II) chloride" and $[Be(H_2O)_4]SO_4$ is named "tetraquoberyllium (II) sulfate."

The number of each type of simple coordinate group is designated by the prefixes *mono-* (for 1), *di-* (for 2), *tri-* (for 3), etc. (see table of *Numerical Prefixes*); e.g., the compound $[SnCl_3(OH)(H_2O)_2]$ is named *tri*chlorohydroxo*di*aquotin (IV), the negative groups being listed first in alphabetical order prior to appending the numerical prefixes. The number of complex coordinated groups is designated by a prefix *bis-* (for 2), *tris-* (for 3), *tetrakis-* (for 4), *pentakis-* (for 5), etc. If the name of a coordinated group normally contains a numerical prefix (e.g., ethylene*di*amine) it is confusing to use the usual numerical prefixes to denote the number of these groups in the coordination sphere. Thus for two ethylenediamine molecules, "*bis*(ethylenediamine)" is preferred over "*di*ethylenediamine." Accordingly, the compound $[Co(H_2N{\cdot}C_2H_4{\cdot}NH_2)_3]Br_3$ is named tris(ethylenediamine)cobalt (III) bromide. Parentheses are used in writing the names of coordination compounds and may or may not appear in the formulas; brackets are used only in writing the formulas. For example, bis(tripyridyl) copper (II) chloride is the name of the compound $[Cu(C_5H_4N{\cdot}C_5H_3N{\cdot}C_5H_4N)_2]Cl_2$.

If the coordination occurs in the anion, the root of the name of the central element is given last with the suffix *-ate* appended; e.g., $K_3[Fe(CN)_6]$, potassium ferricyanide, is named potassium hexacyanoferr*ate* (III); $[K_4Fe(CN)_6]$, potassium ferrocyanide, is named potassium hexacyanoferr*ate* (II). The valence of iron in each of these two compounds is shown by means of the Roman numeral following each name. If the coordination occurs in the cation, the central element is designated *last in the cation portion* of the name; e.g., $[Pt(NH_3)_4][Pt(Cl)_4]$ is tetrammine*platinum* (II) tetrachloroplatinate (II). Geometrical isomers are designated as *cis-* and *trans-* (or *1,2-* and *1,3-*, respectively) if planar, and *1,2-* and *1,6-* if octahedral. Optical isomers are designated as *d-*, *l-*, or *meso-* written before the name of the compound.

If solvation occurs, other than as coordination in the cation, the number of such additional solvate molecules is designated with an Arabic numeral prefixed to the name of the solvate; e.g., $CuSO_4{\cdot}5H_2O$, because of common usage, may be named *copper sulfate 5-hydrate;* named strictly according to its true formula, $[Cu(H_2O)_4]{\cdot}SO_4{\cdot}H_2O$, it is *tetraquocopper* (II) *sulfate 1-hydrate.*

PHYSICAL CONSTANTS OF

Formula Weights are based upon the International Atomic Weights of 1955 and are computed to the nearest hundredth.

Refractive Index, where given for a uniaxial crystal, is for the ordinary (ω) ray; where given for a biaxial crystal, the index given is for the median (β) value. The other indices may be found by referring to the table *Index of Refraction.* Unless otherwise specified, the index is given for the sodium D-line ($\lambda = 589.3 m\mu$).

Specific Gravity values are given at room temperatures (15° to 20°C) unless otherwise indicated by the small figures which follow the value; thus, "$5.6^{18°}$" indicates a specific gravity of 5.6 for the substance at 18°C referred to water at 4°C. In this table the values for the specific gravity of gases are given with reference to air (A) = 1, or hydrogen (D) = 1.

Melting Point is recorded in a certain case as "82 d." and in some other case as "d. 82", the distinction being made in this manner to indicate that the former is a melting point with decomposition at 82°C, while in the latter decomposition only occurs at 82°C. Where a value such as "$-2H_2O$, 82" is given it indicates loss of two moles of water per formula weight of the compound at a temperature of 82°C.

Boiling Point is given at atmospheric pressure (760 mm of mercury) unless otherwise indicated; thus, "82^{15mm}" indicates the boiling point is 82°C when the pressure is 15 mm.

Solubility is given in parts by weight (of the formula shown at the extreme left) per 100 parts by weight of the solvent; the small superscript indicates the temperature. In the case of gases the solubility is often expressed in some manner as "$5^{10°}$ cc" which indicates that at 10°C, 5 cc of the gas are soluble in 100 grams of the solvent. The symbols of the common mineral acids: H_2SO_4, HNO_3, HCl, etc., represent dilute aqueous solutions of these acids. See also special tables on *Solubility.*

Synonyms listed at the bottom of each page include common or trade names as well as alternate chemical names for compounds to be found in the main body of the table but under a different name. The number following the name refers to the

Abbreviations used in the table

a., acid
A., specific gravity with reference to air = 1
abs., absolute
ac., acetic acid
amt., acetone
al., 95% ethyl alcohol
alk., alkali (i. e. aq. NaOH or KOH)
am., amyl (C_5H_{11})
amor., amorphous
anh., anhydrous
aq., aqueous or water
aq. reg., aqua regia
atm., atmosphere or 760 mm of mercury pressure
bk., black
brn., brown
bz., benzene
c., cold
cb., cubic
cc, cubic centimeter
chl., chloroform
col., colorless or white
conc., concentrated
cr., crystals or crystalline
d., decomposes
D., specific gravity with reference to hydrogen = 1
d. 50, decomposes at 50°C; 50d., melts at 50°C with decomposition
deliq., deliquescent
dil., dilute
dk., dark
eff., effloresces or efflorescent
et., ethyl ether
expl., explodes
gel., gelatinous
gly., glycerol, (glycerine)
gn., green
h., hot

SHORT GLOSSARY OF ORGANIC CHEMICAL NOMENCLATURE

The following rules for naming organic compounds and the examples given in explanation are not intended to cover all of the possible cases. For a more comprehensive and detailed description see Beilstein: *Handbuch der Organischen Chemie*, 4th edition, and Patterson: *Definitive Report of the Commission on the Reform of the Nomenclature of Organic Chemistry, Jour. Am. Chem. Soc. 55, 3905* (1933); *News Edition, Ind. Eng. Chem. 14, 486* (1936).

HYDROCARBONS—The saturated open-chain hydrocarbons (C_nH_{2n+2}) have names ending in *ane*. The first four are: *methane* (CH_4); *ethane* (C_2H_6); *propane* (C_3H_8); and, *butane* (C_4H_{10}). Beginning with *pentane* (C_5H_{12}) the prefix (*e.g. penta*) indicates the number of carbon atoms; for example, octane, C_8H_{18}; nonatriacontane, $C_{39}H_{80}$. See special table of *Numerical Prefixes*. Saturated monocyclic hydrocarbons (C_nH_{2n}) have the corresponding names of the open-chain hydrocarbons (C_nH_{2n+2}) preceded by the prefix *cyclo;* for example, cyclopropane (C_3H_6); cyclopentane (C_5H_{10}). The straight (unbranched) chains are termed *normal* (abbreviated: *n*); the grouping $(CH_3)_2CH-$ in a chain is termed *iso;* for example, $CH_3(CH_2)_2CH_3$ is *n*-butane; $(CH_3)_2CHCH_3$ is *iso*-butane. Branched-chain hydrocarbons are often named as derivatives of some relatively simple hydrocarbon by stating what radicals* are attached to the simple hydrocarbon; for example, $CH_3CH_2CH_2CH_3$, which is *n*-butane, may also be named: methyl-ethyl-methane since a methyl radical (CH_3) and an ethyl radical (C_2H_5) are replacing the two hydrogen atoms of the original methane molecule, the carbon atom of which is printed in bold face type. Similarly $(CH_3)_2\mathbf{C}HCH_3$, which is *iso*-butane, would be named trimethyl-methane, the carbon atom printed in bold face type being the methane carbon atom corresponding to this name. In this system of naming, a compound might be given any one of several names depending upon which carbon atom is selected; for example, $CH_3CH_2CH_2CH_2CH_3$ might be given any one of the following names: diethyl-methane; methyl-propyl-methane; butyl-methane.

In 1892 an international congress of chemists assembled in Geneva, Switzerland, to devise a uniform and scientific system of nomenclature. This *Geneva system* with modifications proposed at various times is the modern *systematic naming.* According to this system a hydrocarbon is named as a derivative of the normal compound corresponding to the longest chain of carbon atoms in the molecule. The word *normal* is usually omitted, but implied, so that the simple unqualified systematic name always means the compound with the normal constitution; for example, *n*-butane, $CH_3CH_2CH_2CH_3$, is simply butane; iso-butane, $(CH_3)_2CHCH_3$, is 2-methyl-propane. The numeral *2* placed before** the word *methyl* indicates that the methyl radical is attached to the second carbon atom in the longest chain which, in this example, is of three carbons in length and, therefore, a propane. In cases where several different side chains are attached the order of stating them is either according to increasing complexity (e.g., methyl, then ethyl, then propyl, followed by butyl, etc.) or, according to alphabetical order (e.g., butyl, then ethyl, then methyl, followed by propyl, etc.) Where branching occurs in a side chain and for other cases of ambiguity, or if a simpler name would result, then a chain is selected as the fundamental unit which admits of the maximum of substitutions. A detailed discussion of this and other exceptions caused by very complicated structures is beyond the scope of this exposition and the reader is referred to the references given below the title of this section.

UNSATURATED HYDROCARBONS AND UNSATURATION—Hydrocarbons with one double bond (C_nH_{2n}) are named by adding the suffix *ene* to the name of the corresponding alkyl radical (C_nH_{2n+1})*; for example, $CH_2{:}CH_2$ is ethylene; $CH_3CH{:}CH_2$ is propylene. Just as the saturated hydrocarbons may be named as

*See Radicals in this section and also a special section Names and Formulas of Organic Radicals.

**The numbering is such that the lowest numbers are obtained; e.g., $CH_3CH_2CH_2CH(CH_3)_2$ is 2-methylpentane and not 4-methylpentane. Usage varies as to the position in the word for the numerals not only in the case of the hydrocarbons but also with other types such as alcohols, aldehydes, ketones, etc. Some writers place them before, some after, the parts of the name to which they refer. In Beilstein a combination is used wherein numbers placed after are enclosed in parenthesis and those placed before are not; e.g., primary isobutyl alcohol is named: 2-methyl-butanol-(1).

derivatives of methane, so these C_nH_{2n} hydrocarbons may be named as derivatives of ethylene; for example, $CH_3CH{:}CHCH_3$ which is a butylene, may also be named *sym*-dimethyl-ethylene since two methyl radicals (CH_3) are replacing two hydrogen atoms of the original ethylene molecule, the carbon atoms of which are printed in bold face type. Similarly $(CH_3)_2C{:}CH_2$, also a butylene, would be named *uns*-dimethyl-ethylene. The italicized prefixes *sym* and *uns* are abbreviations for *symmetrical* and *unsymmetrical*, respectively, and refer to the symmetrical or unsymmetrical manner in which the two methyl radicals are attached to the ethylene residue.

In the systematic naming, the longest chain is selected as in the case of the saturated hydrocarbons and the compound is named by replacing the *ane* ending of the corresponding saturated hydrocarbon with the ending *ene;* for example, $CH_3CH{:}CHCH_3$ is 2-butene. The numeral 2 indicates that the double bond is between the second and third carbon atoms. Similarly $(CH_3)_2C{:}CH_2$ is 2-methyl-1-propene** or 2-methyl-propene-(1), because a methyl group is on the second carbon atom, and the double bond is between the first and second carbon atoms in a chain of three carbon atoms. Where more than one double bond occurs in the molecule a numerical prefix is added to the ending *ene;* for example, isoprene, $CH_2{:}C(CH_3)CH{:}CH_2$ is 2-methyl-1,3-butadiene because the longest chain contains four carbon atoms with a methyl radical (CH_3) on the second carbon atom and double bonds between the first and second carbon atoms, and between the third and fourth carbon atoms of the four-carbon chain Similarly benzene would be named cyclohexa-1,3,5-triene.

Hydrocarbons with one triple bond (C_nH_{2n-2}) may be named as derivatives of acetylene ($CH{:}CH$); for example, $CH_3C{:}CH$ which is allylene, may also be named methyl-acetylene. In the systematic naming the same scheme is used as with the double bond compounds except that the ending becomes *yne* or *ine*. Thus, allylene is 1-propyne or 1-propine. The Greek letter Δ is often used to indicate unsaturation; the numbers following it indicate the positions of the unsaturated linkings.

Unsaturation in compounds other than the hydrocarbons, such as alcohols, aldehydes, ketones, etc., is indicated in the same general manner by use of *ene, diene, ine*, etc.; for example, allyl alcohol, $CH_2{:}CHCH_2OH$, is Δ^1-propenol-(3)***.

ALCOHOLS—Alcohols are commonly named from the radical to which the hydroxyl radical (OH) is attached; for example, CH_3OH is methyl alcohol; $C_6H_5CH_2OH$ is benzyl alcohol. As in the case of the hydrocarbons, a complex alcohol may be named as the derivative of some relatively simple alcohol. When alcohols are named as derivatives of methyl alcohol the latter is commonly given the name of *carbinol;* for example, $(CH_3)_2CHOH$ is dimethyl carbinol because two of the hydrogen atoms in methyl alcohol have been replaced by two methyl radicals; similarly benzyl alcohol, $C_6H_5CH_2OH$, is phenyl carbinol. The adjectives *primary, secondary,* and *tertiary* are often used in connection with alcohols and refer to alcohol groupings which are of the type $-CH_2OH$, $=CHOH$, $\equiv COH$, respectively; for example, $C_3H_7CH_2OH$ is a primary butyl alcohol; $CH_3CH(OH)C_2H_5$ is a secondary butyl alcohol; $(CH_3)_3COH$ is a tertiary butyl alcohol.

In the systematic naming the hydroxyl radical is indicated by the ending *ol* and its position of attachment by an arabic numeral; for example, $C_2H_5CH_2CH_2OH$ is 1-butanol; $(CH_3)_3COH$ is 2-methyl-2-propanol because a methyl radical and an hydroxyl radical are both attached to the second carbon atom in a chain of three carbon atoms.** Two, three, etc., hydroxyl radicals in a molecule are indicated by the endings *diol, triol,* etc.; for example, glycol, CH_2OHCH_2OH is 1,2-ethandiol.

ETHERS—Ethers are most commonly named by adding the word *ether* to the name of the radicals connected by the ether oxygen atom; for example, $(C_2H_5)_2O$ is ethyl ether or diethyl ether; $CH_3OC_2H_5$ is methyl-ethyl ether. Often the name is such as to designate the presence of an alkoxy (OR) group; for example, $CH_3OC_6H_5$ is methoxy benzene.

ALDEHYDES—Aldehydes are most frequently named by dropping the ending *ic* from the name of the acid to which they are directly oxidizable and adding the suffix *aldehyde;* for example, CH_3CHO is named acetaldehyde because it is directly

***In this case the final vowel *e* of the ending *ene* has been dropped from the name because it is followed by the vowel *o* of the ending *ol* which is used to indicate the alcoholic hydroxyl radical.

oxidized to acetic acid, CH_3CO_2H; similarly C_6H_5CHO is named benzaldehyde to show its relationship to benzoic acid. Sometimes aldehydes are named in a manner to show a relationship to some simpler aldehyde such as formaldehyde, HCHO; for example, CH_3CHO is methyl formaldehyde because the methyl radical has replaced the hydrogen atom in formaldehyde; similarly C_6H_5CHO is named phenyl formaldehyde. In the systematic naming the ending *al* indicates an aldehyde radical (CHO); for example, CH_3CHO is ethanal; $(CH_3)_2CHCHO$ is 2-methyl-1-propanal.**

KETONES—Ketones are most often named by adding the word *ketone* to the names of the radicals connected to the CO radical; for example, $(CH_3)_2CO$ is dimethyl ketone; $CH_3COCH(CH_3)_2$ is methyl-isopropyl ketone. The systematic names of the ketones differ from those of the alcohols and the aldehydes (*q. v.*) only in the termination *one* which is added to the name of the hydrocarbon; for example, $(CH_3)_2CO$ is propanone; $CH_3COCH(CH_3)_2$ is 2-methyl-butanone-(3).**

ACIDS—The common names of the normal carboxylic acids are derived from words having some relation to their natural occurrence or their properties; for example, formic, from ants (*Formicidae*); butyric, from butter; tannic, from the tanning property. Sometimes acids are named in a manner to show a relationship to some simpler acid such as acetic, CH_3CO_2H; for example, pivalic acid, $(CH_3)_3CCO_2H$, is tri-methyl-acetic acid because three methyl radicals (CH_3) are replacing the three hydrogen atoms in acetic acid. The systematic names are derived by adding the suffix *oic* and the word *acid* to the root of the name for the hydrocarbon of the *same number of carbon atoms;* for example, isovaleric acid, $(CH_3)_2CHCH_2CO_2H$, is 2-methyl-butanoic-4-acid; succinic acid, $(CH_2CO_2H)_2$, is butan-1,4-dioic acid. In compounds where such a naming would be awkward the carboxyl radical (CO_2H) is considered as a substituting group and the acid named accordingly; for example, citric acid, $HO_2CCH_2C(OH)(CO_2H)CH_2CO_2H$, is 2-hydroxy-propan-1,2,3-tricarboxylic acid.**

ESTERS AND SALTS—To the name of the alcoholic (or phenolic) radical, or the metal, is added the name of the acid modified to end in *ate;* for example, the ester of ethyl (C_2H_5) alcohol and acetic acid, $CH_3CO_2C_2H_5$, is ethyl acetate; the sodium salt of acetic acid, CH_3CO_2Na, is sodium acetate. To emphasize the ester structure they are often named as follows: acetic acid ethyl ester for ethyl acetate; malonic acid diethyl ester for diethyl malonate, $CH_2(CO_2C_2H_5)_2$.

ACID DERIVATIVES—The most common types in this classification are the anhydrides $(RCO)_2O$; halides ROCl; amides $RCONH_2$; amidoximes $RC(:NOH)NH_2$; amidines $RC(:NH)NH_2$; imides $R(CO)_2NH$; nitriles RCN. They are named by adding the endings *anhydride, chloride* (or other *halide*), *amide, amidoxime, amidine, imide, nitrile,* respectively, to the name of the acid or acid radical* (e.g., acetyl, acet, or aceto for the acid radical CH_3CO); for example, acetic anhydride, $(CH_3CO)_2O$; acetyl chloride, CH_3COCl; acetamide, CH_3CONH_2; acetamidoxime, $CH_3C(:NOH)NH_2$; acetamidine, $CH_3C(:NH)NH_2$; acetonitrile, CH_3CN; succinimide, $(CH_2CO)_2NH$. In compounds where such a naming would be awkward the modified carboxyl group is considered as a substituting group and named carbonamide, carbonamidine, carbonitrile, etc.

AMINES—Amines are most often named by adding the suffix *amine* to the name of the radical (or radicals) replacing one (or more) hydrogen atoms in ammonia (NH_3); for example, CH_3NH_2 is methylamine; $CH_3NHC_2H_5$ is methyl-ethylamine. Sometimes amines are named in a manner to show a relationship to some other simpler (or well-known) amine; for example, $C_6H_5NHCH_3$ is methylaniline; $C_6H_5N(CH_3)_2$ is named dimethylaniline to show the relationship to aniline, $C_6H_5NH_2$. In the systematic names the amino (NH_2) or modified amino (NHR, and NR_2) group is considered as a substituting group of the hydrocarbon; for example, $(CH_3)_2CHNH_2$ is 2-aminopropane; $(CH_3)_2CHCH_2NHCH_3$ is 2-methyl-1-methylamino-propane.

RADICALS—Alkyl radicals (C_nH_{2n+1}) are univalent groups derived by removal of one hydrogen atom from saturated hydrocarbons. They are named by replacing the ending *ane* of the corresponding hydrocarbon with the ending *yl;* for example, C_2H_5- is ethyl derived from ethane (C_2H_6); $CH_3CH_2CH_2$- is propyl; $(CH_3)_2CH$- is isopropyl.

ORGANIC CHEMICAL NOMENCLATURE

Univalent radicals derived from unsaturated aliphatic hydrocarbons have the endings *enyl; ynyl; dienyl;* etc.; for example, CH_2:CH- commonly called *vinyl* is also ethenyl; CH:C- is *ethynyl;* CH_2:CH-CH:CH- is *buta-1,3-dienyl.* In the aromatic series the corresponding *aryl* radicals are named in a similar manner; for example, C_6H_5- is *phenyl;* C_6H_4 = is phenylene; $CH_3C_6H_4$- is tolyl.

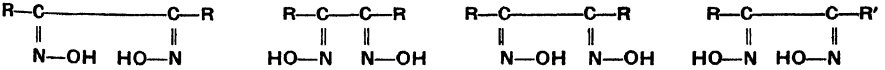
Bivalent radicals derived by removal of two hydrogen atoms from the *same carbon atom* are sometimes named in a manner similar to the corresponding aldehyde; for example, CH_3CH = is acetal; C_6H_5CH = is benzal. In the systematic naming the ending *ylidene* is used to replace the ending *ane* of the corresponding saturated hydrocarbon; for example, CH_3CH = is ethylidene; somewhat analogous is C_6H_5CH = when named benzylidene.

Acid radicals, derived by removal of OH from the carboxyl group (COOH), are named by replacing the ending *ic* of the acid name with the ending *yl;* for example, CH_3CO- is acetyl (from acetic) or ethanoyl (from ethanoic).

See also the special table NAMES AND FORMULAS OF ORGANIC RADICALS.

RING COMPOUNDS—Positions of substituting groups on the various rings are usually indicated by a system of numbering. In the benzene series of compounds disubstitution positions are often indicated by the terms *ortho* (abbreviated *o*) for the 1,2-positions; *meta* (abbreviated *m*) for the 1,3-positions; *para* (abbreviated *p*) for the 1,4-positions. In cases of trisubstitution the terms *vicinal* (*vic*), *unsymmetrical* (*uns*) and *symmetrical* (*sym*) are often employed to indicate the positions 1,2,3; 1,3,4; and 1,3,5, respectively. In the naphthalene series of compounds, especially in the older literature, disubstitution positions are sometimes indicated by the terms *ortho, meta,* and *para* with the same significance as in the benzene series, and by the terms *ana* for the 1,5-positions; *epi* for the 1,6-positions; *kata* for the 1,7-positions; *peri* for the 1,8-positions; *amphi* for the 2,6-positions; and *pros* for the 2,7-positions.

See also the special table ORGANIC RING SYSTEMS.



PREFIXES AND SUFFIXES

-al, a suffix indicating the presence of an *aldehyde group* (-CHO), as in chlor*al*, Cl_3C-CHO; or penten*al*, $CH_3(CH_2)_3$-CHO.*

allo-, a prefix indicating the compound to be a close relative, an isomer, or a variety of the compound to the name of which it is prefixed, as *allo*caffeine. In cases of ethylenic isomerism it is prefixed to the name of the more stable form into which the compound can be converted on heating; thus, fumaric acid is *allo*maleic acid since it is the stable isomer formed on heating maleic acid.

alpha-, beta-, gamma-, etc., usually written as letters of the Greek alphabet (α, β, γ, etc.) to indicate the first, second, third, etc., positions of substitution respectively, as in α-aminopropionic acid for $CH_3 \cdot CH(NH_2) \cdot CO_2H$ where the carbon atom attached to the CO_2H group is considered the α-carbon atom. See also the definition below for *omega* (ω). See also the numbering in the section ORGANIC RING SYSTEMS.

amphi-, a prefix used with disubstitution products of naphthalene to indicate the 2,6-positions. It is also used in naming certain stereoisomers of dioximes; thus,

syn-form *anti*-form *amphi*-form *amphi*-form

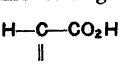
-ane, a suffix usually indicating a saturated (paraffin) hydrocarbon, C_nH_{2n+2}, as in pent*ane*, C_5H_{12}.* It is also used to indicate saturated parent compounds in the cyclic series, as camph*ane*, $C_{10}H_{18}$; or diox*ane*, $C_4H_8O_2$.

anti-, a term used in certain cases of stereoisomerism to indicate an opposed arrangement of groups or atoms, as in *anti*tartaric (mesotartaric) acid. It is often

* See this on preceding pages.

employed to *amphi* and *syn*. See also

syn-Phenyl tolyl ketoxime



anti-Phenyl tolyl ketoxime

apo-, a prefix indicating a compound which is related to, or formed from, the compound to the name of which it is prefixed, as *apo*morphine.

-ase, a suffix used in forming the name of an enzyme. Usually the suffix is added to the name, or a part of the name, of a substance upon which the enzyme acts; e.g., malt*ase*.

-ate, a suffix used to denote an ester or a salt; e.g., ethyl acet*ate*; or sodium acet*ate*.*

cis, a term used in cases of *cis-trans* (i.e., ethylenic) stereoisomerism to indicate that certain elements or groups are on the *same side* of the molecule; e.g.,

cis-form

trans-form

d, an abbreviation for *dextro* and usually indicating that a compound is *dextrorotatory*. Exceptions to this meaning are to be noted in certain cases of nomenclature; e.g., *d*-fructose, although levorotatory, is so named because of its relation in configuration to *d*-glucose and *d*-mannose; conversely, *l*-fructose, similarly related to *l*-glucose and *l*-mannose, is dextrorotatory.

-diene, a suffix indicating the *unsaturation* of two ethylenic (i.e., two double bond) linkages; e.g., a diolefin, C_nH_{2n}, as penta*diene*, $CH_3 \cdot CH{:}CH \cdot CH{:}CH_2$.*

-diine, or ***-diyne***, a suffix indicating the *unsaturation* of two acetylenic (i.e., two triple bond) linkages; e.g., a diacetylene, C_nH_{2n-6}, as buta*diyne*, $CH{:}C \cdot C{:}CH$.*

-dioic, a suffix indicating a *dicarboxylic* (two $-CO_2H$) acid; e.g., pentan*dioic* acid, $HO_2C \cdot (CH_2)_3 \cdot CO_2H$.*

-diol, a suffix indicating the presence of *two alcohol* (two hydroxyl) groups; e.g., pentan*diol*, $HO \cdot CH_2 \cdot (CH_2)_3 \cdot CH_2OH$.*

dl, an abbreviation for *dextro-levo* indicating a substance composed of equal parts of the dextro- and levo-optical isomers of a compound.

-ene, a suffix indicating the *unsaturation* of one ethylenic (i.e., one double bond) linkage; e.g., an olefin, C_nH_{2n}, as pent*ene*, $CH_2{:}CH \cdot C_3H_7$.* It is often used as a suffix in naming aromatic hydrocarbons; e.g., ben*zene*, tolu*ene*, naphthal*ene*, etc.

epi-, a prefix used with disubstitution products of naphthalene to indicate the 1,6-positions. See *RING COMPOUNDS* preceding. It is also prefixed to the name of an aldose, or related compound, to indicate an isomer that differs from the aldose only in the arrangement of the group about the α-carbon atom (the carbon atom next to the aldehyde group); thus, mannose is also called *epi*glucose. It is also used as a prefix to indicate a *bridge* or intramolecular connection, as in *epi*chlorohydrin, $O \cdot CH_2 \cdot CH \cdot CH_2Cl$.

eso-, a prefix indicating that substitution groups are *attached to the ring*, as *eso*-trinitromesitylene for the 2,4,6-trinitro derivative of mesitylene. See also *exo-*.

exo-, a prefix indicating that substitution groups are *attached to the side chain*, as *exo*-nitrotoluene for phenyl-nitromethane, $C_6H_5 \cdot CH_2 \cdot NO_2$. See also *omega-* and *eso-*.

homo-, a prefix indicating a homologue of the compound to the name of which it is prefixed and usually differing by having one more CH_2 in the formula; e.g., *homo*salicylic acid, $CH_3 \cdot C_6H_3(OH)CO_2H$.

i or in, an abbreviation for *inactive* and indicating that the substance exhibits no activity towards polarized light. See also *dl*.

-ic, see ***-oic***.

*See this on preceding pages.

-in, a suffix used in forming the names of fats (i.e., the glycerides or esters of glycerol), the suffix being used to replace the *ic* ending of the name of the fatty acid forming the glyceride; e.g., tributyr*in*, $(C_3H_7CO)_3C_3H_5O_3$. It is often used as a suffix in the names of proteins and of glucosides; e.g., album*in* and amygdal*in*, resp. See also *i* above.

-ine, a suffix often used in forming the names of basic compounds such as amines, alkaloids, and amino acids; e.g., anil*ine*, quin*ine*, and glyc*ine*, resp. See also *-yne.*

-ite, a suffix used in various ways; thus, for esters of the *ous* acids, e.g., amyl nitr*ite*, $C_5H_{11}O \cdot NO$; for polyhydric alcohols, e.g., mann*ite* (mannitol), $C_6H_8(OH)_6$; for explosives, e.g., cord*ite*, a smokeless powder.

l, an abbreviation for *l(a)evo* and indicating that a compound is levorotatory. See also *d.*

N-, a letter used in the names of certain nitrogen compounds to indicate that the group to which the letter is prefixed has replaced a hydrogen directly attached to a nitrogen atom; e.g., *N*-methylpyrrole, $C_4H_4{:}N \cdot CH_3$. Sometimes the letter is erroneously used to indicate a *normal* compound, as *N*-butane, $CH_3 \cdot CH_2 \cdot CH_2 \cdot CH_3$, instead of a lower case letter for this meaning, as *n*-butane.

N. F., an abbreviation for the publication *National Formulary* which is issued by the *American Pharmaceutical Association* and quoted in Federal and State laws as having equal authority with the *United States Pharmacopoeia.* See also *U. S. P.*

nor-, a prefix indicating the parent compound from which another may be regarded as derived, as *nor*camphor (of which camphor is the 7-methyl derivative). The prefix has also been used to indicate a *normal* compound which is isomeric with the one to the name of which it is prefixed, as *nor*valine which is α-amino-*n*-valeric acid, whereas valine is α-amino-*iso*-valeric acid.

O-, a letter used in names of certain oxygen compounds to indicate that the group to which the letter is prefixed has replaced a hydrogen directly attached to an oxygen atom; e.g., *O*-ethyl phenol (phenetole), $C_2H_5 \cdot O \cdot C_6H_5$.

-oic, a suffix indicating a carboxylic (CO_2H) *acid;* e.g., pentan*oic* acid.* Often the suffix *-ic* is used in forming the name of an acid; e.g., acet*ic* acid.

-ol, a suffix indicating an *hydroxyl group* (OH) as in an alcohol,* e.g., pentan*ol;* or in a phenol, e.g., resorcin*ol,** $C_6H_4(OH)_2$.

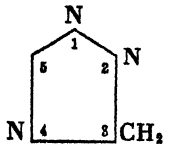
-ole, a suffix used in various ways; thus, for phenolic ethers, e.g., phenet*ole*, $C_2H_5 \cdot O \cdot C_6H_5$; for certain aldehydes, e.g., oenanth*ole*, $CH_3(CH_2)_5 \cdot CHO$; for five-membered rings, usually heterocyclic, e.g., pyrr*ole*, C_4H_5N, or oxaz*ole*, C_3H_3ON.

omega-, a prefix indicating a substitution group *on the last carbon* of a side chain, as *omega*-nitrostyrene for $C_6H_5 \cdot CH{:}CH \cdot NO_2$. It is most often indicated by the Greek letter omega (ω), as ω-nitrostyrene.

-one, a suffix indicating the presence of a *ketone group* (:CO), as in propan*one,** $CH_3 \cdot CO \cdot CH_3$; or acetophen*one*, $CH_3 \cdot CO \cdot C_6H_5$.

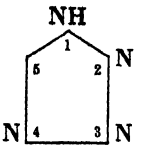
-ose, a suffix usually indicating a *carbohydrate;* e.g., gluc*ose*, $C_6H_{12}O_6$; cellul*ose*, $(C_6H_{10}O_5)_x$. It is also used in naming the primary alteration or hydrolytic products of proteins; e.g., album*ose.*

par(a)-, a prefix or an adjective used to indicate that the substance is related in some way, as a polymer, an isomer, etc., of the compound to whose name it is attached; e.g., *para*ldehyde, *para*lactic acid. See also its significance when used in showing position of substituents in naming *RING COMPOUNDS.**



poly-, a prefix indicating a polymer of the compound to the name of which it is prefixed, as *poly*styrene, $(C_8H_8)_x$.

prim., an abbreviation for *primary* and indicating a replacement to the first degree; e.g., a primary amine $(R \cdot NH_2)$ where only one of the three hydrogens in ammonia has been replaced by a group (R) of atoms. It is frequently used in the designation of certain *alcohols.**



pseudo-, a prefix indicating an isomerism with, or some other relation to, the compound to the name of which it is prefixed, as *pseudo*tropine. It is sometimes indicated by the Greek letter *psi* (ψ); e.g., ψ-tropine.

* See this on preceding pages.

NAMES AND FORMULAS OF ORGANIC RADICALS

Reprinted from *Chemical Abstracts*, Decennial Index, Subjects, 1917-1926, by permission.

Name	Formula
Acenaphthenyl (from acenaphthene)	$C_{12}H_9$–
Acetamido	CH_3CONH–
Acetenyl cf. ethinyl	.....
Acetimido	$CH_3C(:NH)$–
Acetonyl	CH_3COCH_2–
Acetonylidene	CH_3COCH:
Acetoxy	$CH_3CO{\cdot}O$–
Acetyl	CH_3CO–
Acetylene	:CHCH:
Acridyl (from acridine)	$C_{13}H_8N$–
Acrylyl	CH_2:$CHCO$–
Adipyl	$-OC(CH_2)_4CO-$
Alanyl	CH_3CHNH_2CO–
Alkoxy (any alkyl radical attached by oxygen)	$C_nH_{2n+1}O$–
Allyl	CH_2:$CHCH_2$–
β–allyl cf. isopropenyl	.....
Amidoxalyl cf. oxamyl	.....
Amino (amido)	H_2N–
Amoxy	$CH_3(CH_2)_4O$–
Amyl	$CH_3(CH_2)_4$–
tert-Amyl	$(C_2H_5)(CH_3)_2C$–
Amylidene	$CH_3(CH_2)_3CH$:
Anilino	C_6H_5NH–
Anisal	*p*–$CH_3OC_6H_4CH$:
Anisoyl	*p*–$CH_3OC_6H_4CO$–
Anisyl	(*o*, *m* or *p*) $CH_3OC_6H_4$–
Anisylidene cf. anisal	.....
Anthranilo	*o*–$C_6H_4CO{\cdot}N$–
Anthranoyl	*o*–$H_2NC_6H_4CO$–
Anthraquinonyl (from anthraquinone)	two isomers
Anthryl (from anthracene)	five isomers
Anthrylene (from anthracene)	$C_{14}H_8$:(11 isomers)
Antipyryl (from antipyrene)	$CO{\cdot}N(C_6H_5){\cdot}N(CH_3){\cdot}C(CH_3):C$–
Arseno	–As:As–
Arsino (from arsinic acid)	$(HO)OAs$:
Arsinoso	O:As–
Arsono (from arsonic acid)	$(HO)_2OAs$–
Arsyl	H_2As–
Arsylene	HAs:
Asaryl	(2,4,5) $(CH_3O)_3C_6H_2$–
Asparagyl	$H_2NCOCH_2CHNH_2{\cdot}CO$–
Aspartyl	$-COCH_2CHNH_2CO-$
Auro	Au–
Azimino (azimido)	–N:NNH–
Azido cf. triazo	.....
Azino	:N·N:
Azo	–N:N–
Azoxy	–NO:N–
Benzal	C_6H_5CH:
Benzamido	C_6H_5CONH–
Benzenyl	C_6H_5C:
Benzidino (from benzidine)	$H_2NC_6H_4C_6H_4NH$–
Benzilyl	$(C_6H_5)_2C(OH)CO$–
Benzimidazolyl (from benzimidazole)	$C_7H_5N_2$–
Benzimido	$C_6H_5C(:NH)$–
Benzofuryl (from benzofuran)	C_8H_5O
Benzohydryl	$(C_6H_5)_2CH$–
Benzohydrylidene cf. diphenylmethylene	.....
Benzopyranyl (from benzopyran)	C_9H_7O(2–α–, etc.)
Benzoxazolyl (from benzoxazole)	C_7H_4NO–
Benzoxy	$C_6H_5CO{\cdot}O$–
Benzoyl	C_6H_5CO–
Benzoylene	$-C_6H_4CO-$
Benzyl	$C_6H_5CH_2$–
Benzylidene cf. benzal	.....
Biphenylene	$-C_6H_4{\cdot}C_6H_4-$
Biphenylenedisazo	$-N:NC_6H_4C_6H_4N:N-$
Bornyl (from borneol)	$C_{10}H_{17}$–
Boryl	O:B–
Bromo	Br–
Δ^1-Butenyl	$CH_3CH_2CH:CH$–
Δ^2-Butenyl	$CH_3CH:CHCH_2$–
Δ^3-Butenyl	$CH_2:CH(CH_2)_2$–
Butoxy	$CH_3(CH_2)_2O$–
Butyl	$CH_3(CH_2)_3$–
sec-Butyl	$(C_2H_5)(CH_3)CH$–
tert-Butyl	$(CH_3)_3C$–
Butylene	$-CH_2CH_2CH_2CH_2-$ (1, 4–form)
Butylidene	$CH_3(CH_2)_2CH$:
Butyryl	$CH_3(CH_2)_2CO$–
Camphanyl (from camphane)	$C_{10}H_{17}$–(3 isomers)
Camphoroyl (from camphoric acid)	$C_{10}H_{14}O_2$:
Camphoryl (from camphor)	$C_{10}H_{15}O$–
Camphorylidene (from camphor)	$C_{10}H_{14}O$:

NAMES AND FORMULAS OF ORGANIC RADICALS

Name	Formula
Carbamido	$H_2NCONH-$
Carbamyl	H_2NCO-
Carbanilino cf. phenylcarbamyl	.....
Carbazyl (from carbazole)	$C_{12}H_8N-$ (5 isomers)
Carbethoxy	$C_2H_5O{\cdot}CO-$
Carbomethoxy	$CH_3O{\cdot}CO-$
Carbonyl	OC:
Carbonyldioxy	$-O{\cdot}CO{\cdot}O-$
Carboxy	$-CO{\cdot}OH$

Methene cf. methylene	.....
Methenyl	HC:
Methionyl	$CH_2(SO_2)_2$:
Methoxy	CH_3O–
Methyl	CH_3–
Methylene	H_2C:
Methylenedioxy	$–O·CH_2·O$–
Methylol cf. hydroxymethyl	.....
Naphthal	$C_{10}H_7CH$:
Naphthalimido (from naphthalic acid)	$C_{10}H_6(CO)_2N$–
Naphthenyl	$C_{10}H_7C$:
Naphthobenzyl	$C_{10}H_7CH_2$–
Naphthoxy	$C_{10}H_7O$–
Naphthoyl	$C_{10}H_7CO$–
Naphthyl (1 or 2)	$C_{10}H_7$–
Naphthylene	$C_{10}H_6$:
Naphthylidene	$C_6H_4CH_2CH:CH·C$: (1(4)–), etc.
Nitramino	$O_2N·NH$–
Nitrilo	N:
Nitro	O_2N–
aci-Nitro cf. isonitro	.....
Nitroso	ON–
Norcamphanyl (from norcamphane)	C_7H_{11}–
Octyl	$CH_3(CH_2)_7$–
Oxalyl	$–OC·CO$–
Oxamido	$H_2NCO·CONH$–
Oxamyl	$H_2NCO·CO$–
Oximido cf. isonitroso	.....
Oxy cf. epoxy and keto	–O–(used as a connective)
Pentamethylene	$–CH_2(CH_2)_3CH_2$–
Pentazyl	N:N·N:N·N–
Pentenyl (like butenyl)	C_5H_9–
Pentyl cf. amyl	.....
Perimidyl (from perimidine)	$C_{11}H_7N_2$–(8 isomers)
Perthio	S:S:
Phenacyl	$C_6H_5COCH_2$–
Phenacylidene	C_6H_5COCH:
Phenanthryl (from phenanthrene)	$C_{14}H_9$–(5 isomers)

NAMES AND FORMULAS OF ORGANIC RADICALS

Name	Formula
Phenanthrylene	$C_{14}H_8$: (several isomers)
Phenenyl	C_6H_3: (*s*-,*as*-,*v*-)
Phenethyl	$C_6H_5CH_2CH_2$–
Phenetidino	$C_2H_5OC_6H_4NH$–
Phenetyl	$C_2H_5OC_6H_4$–(*o*,*m*, or *p*)
Phenoxy	C_6H_5O–
Phenyl	C_6H_5–
Phenylazo	$C_6H_5N{:}N$–
Phenylcarbamido	$C_6H_5NHCONH$–
Phenylene	C_6H_4: (*o*, *m*, or *p*)
Phenylenedisazo	$-N{:}NC_6H_4N{:}N-$(*o*,*m*,*p*)
Phenylidene (*p*)	CH:CH·CH$_2$·CH:CH·C (also *o*-isomer)
Phenylureido cf. phenylcarbamido	.....
Phosphazo	–N:P–
Phosphono	H_2O_3P–
Phthalal	:HC·C_6H_4·CH:
Phthalamido (*o*)	$HO_2C{\cdot}C_6H_4{\cdot}CONH$–
Phthalidene (from phthalide)	$C_6H_4{\cdot}CO{\cdot}O{\cdot}C$:
Phthalidyl	$C_6H_4{\cdot}CO{\cdot}O{\cdot}CH$–
Phthalimido (*o*)	$C_6H_4(CO)_2N$–
Phthalyl (*o*)	–OC·C_6H_4·CO–
Picryl	$(NO_2)_3C_6H_2$–(2,4,6)
Piperidyl (from piperidine)	$C_5H_{10}N$– (4 isomers)
Piperonyl	$(CH_2O_2)C_6H_3CH_2$– (3, 4)
Piperonylidine	$(CH_2O_2)C_6H_3CH$:(3,4)
Pivalyl (from pivalic acid)	$(CH_3)_3C{\cdot}CO$–
Prolyl (from proline)	NH·CH$_2$CH$_2$CH$_2$CH· CO–
Propargyl	HC:C·CH$_2$–
Propenyl	CH$_3$CH:CH–
Propenylidene	CH$_3$CH:C:
Propiolyl	HC:C·CO–
Propionyl	CH$_3$CH$_2$CO–
Propoxy	CH$_3$CH$_2$CH$_2$O–
Propyl (*n*)	CH$_3$CH$_2$CH$_2$–
Propylene	–CH(CH$_3$)CH$_2$–
Propylidene	CH$_3$CH$_2$CH:
Pseudoallyl cf. isopropenyl	.....
as-Pseudocumyl	$(CH_3)_3C_6H_2$–(2,3,5)
s-Pseudocumyl	$(CH_3)_3C_6H_2$–(2,4,5)
v-Pseudocumyl	$(CH_3)_3C_6H_2$–(2,3,6)
Pseudoindyl (from pseudoindole)	C_8H_6N– (7 isomers)
Pyranyl (2-α, 2-γ, 3-α, etc.)	C_5H_5O–
Pyrazolyl (from pyrazole)	$C_3H_3N_2$–(4 isomers)
Pyridyl (from pyridine)	C_5H_4N–(3 isomers)
Pyridylidene 4(1)–	CH:CH·NH·CH:CH·C:
Pyrimidyl (from pyrimidine)	$C_4H_3N_2$–
Pyromucyl	O·CH:CH·CH:C·CO–
Pyrrolidyl (from pyrrolidine)	C_4H_8N– (3 isomers)
Pyrroyl	CH:CH·CH:CH·N·CO–
Pyrryl (from pyrrole)	C_4H_4N– (3 isomers)
Quinolyl (from quinoline)	C_9H_6N– (7 isomers)
Quinonyl (from quinone)	$C_6H_3O_2$–
Quinoxalyl (from quinoxaline)	$C_8H_5N_2$–
Salicyl (*o*)	HO·C_6H_4–
Salicylal (*o*)	HO·C_6H_4·CH:
Salicylyl (*o*)	HO·C_6H_4·CO–
Selenino	(HO)OSe–
Seleno	Se:
Selenocyano	NCSe–
Selenono	HO_3Se–
Selenonyl	$-SeO_2$–
Selenyl	HSe–
Semicarbazido	$H_2NCONHNH$–
Silicono	(HO)OSi–
Silicyl	H_3Si–
Silicylene	H_2Si:
Stannyl	H_3Sn–
Stearyl	$CH_3(CH_2)_{16}CO$–
Stibono	$(HO)_2OSb$–
Styrene	–CH(C_6H_5)CH$_2$–
Styrolene cf. styrene	.....
Styryl	C_6H_5CH:CH–
Succinamyl	$H_2NCOCH_2CH_2CO$–
Succinyl	–OCCH$_2$CH$_2$CO–
Sulfamino	HO_3SNH–
Sulfamyl	H_2NO_2S–
Sulfhydryl cf. mercapto	.....
Sulfino	HO_2S–
Sulfinyl	OS:
Sulfo	HO_3S–
Sulfonamido	$-SO_2NH$–
Sulfonyl	$-SO_2$–
Sulfuryl cf. sulfonyl	.....
Tauryl	$H_2NCH_2CH_2SO_2$–
Telluro	Te:
Terephthalal (*p*)	:HC·C_6H_4·CH:
Tetramethylene cf. 1, 4-butylene	.....
Tetrazyl (from tetrazole)	CHN_4– (2 isomers)
Thiazyl (from thiazole)	C_3H_2NS– (3 isomers)
Thienyl (from thiophene)	C_4H_3S– (2 isomers)

NAMES AND FORMULAS OF ORGANIC RADICALS

Name	Formula
Thio	–S–
Thiocarbonyl	SC:
Thiocyano	NCS–
Thiohydroxy cf. mercapto	.....
Thiol (S replacing *O* in *OH*)	Used in place of "Thio" only when required for distinction
Thiono (S replacing *O* in *CO*)	Used in place of "Thio" only when required for distinction
Thionyl cf. sulfinyl	.....
Thujyl (from sabinane)	$C_{10}H_{17}$– (attached at 2 positions)
Thymyl (from thymol)	HC:C(CH$_3$)·CH:CH· | C(*t*–C$_3$H$_7$):C– |
Toloxy (*o*, *m*, or *p*)	$CH_3C_6H_4O$–
Toluino (*o*, *m*, or *p*)	$CH_3C_6H_4NH$–
Toluyl (*o*, *m*, or *p*)	$CH_3C_6H_4CO$–
α–Toluyl	$C_6H_5CH_2CO$–
Tolyl (*o*, *m*, or *p*)	$CH_3C_6H_4$–
α–Tolyl cf. benzyl	.....
Tolylene	$CH_3C_6H_3$: (6 isomers)
α–Tolylene cf. benzal	.....
Triazeno	$H_2NH:N$–
Triazinyl (from triazine)	$C_3H_2N_3$–
Triazo	N:N·N– |___|
Triazolyl (from triazole)	$C_2H_2N_3$–
Trimethylene	$-CH_2CH_2CH_2$–
Tryptophyl (from tryptophan)	$C_{11}H_{11}ON_2$–
Tyrosyl (from tyrosine)	*p*–HOC$_6$H$_4$CH$_2$CHNH$_2$·CO–
Undecyl cf. hendecyl (in sense $C_{11}H_{23}$–)	.....
Uramino cf. carbamido	.....
Ureido (by some used synonymously with carbamido)	–NHCONH–
Valeryl	$CH_3(CH_2)_3CO$–
Valyl (from valine)	$(CH_3)_2CHCHNH_2CO$–
Vanillal	(CH$_3$O)(HO)C$_6$H$_3$CH: (3, 4)
Vanilloyl	(CH$_3$O)(HO)C$_6$H$_3$CO– (3, 4)
Vanillyl	(CH$_3$O)(HO)C$_6$H$_3$CH$_2$ – (3, 4)
Veratral	$(CH_3O)_2C_6H_3CH$: (3, 4)
Veratroyl	$(CH_3O)_2C_6H_3CO$– (3,4)
Veratryl	$(CH_3O)_2C_6H_3CH_2$– (3, 4)
Veratrylidene cf. veratral	.....
Vinyl	$H_2C:CH$–
Vinylene	–CH:CH–
Vinylidene	$H_2C:C$:
Xanthyl (from xanthene)	$C_{13}H_9O$– (6 isomers)
Xyloyl (from xylic acid)	$(CH_3)_2C_6H_3CO$– (7 isomers)
Xylyl (dimethylphenyl)	$(CH_3)_2C_6H_3$–
Xylylene	$-H_2C·C_6H_4·CH_2$–

FORMULA INDEX

For finding compounds listed in the table: PHYSICAL CONSTANTS OF ORGANIC COMPOUNDS.

The system used in this formula index is essentially the same as that employed in *Richter's Lexikon der Kohlenstoff Verbindungen*. The succession of the elements combined with carbon is as follows: H, O, N, S, F, Cl, Br, I. All the other elements are placed in alphabetical order according to their symbols. The arrangement depends (1) on the number of carbon atoms, (2) on the number of the other elements, which in addition to carbon, are contained in the compounds, (3) on the kind of elements, which in addition to carbon are contained in the molecule, in accordance with the order as stated above, and (4) on the number of atoms of each element which, in addition to carbon, is contained in the compound. Thus 2 III means two carbon atoms combined with three other elements; *e.g.*, $C_2H_2O_2F_2$ 2239, is a compound with 2 carbon atoms and 3 other elements, and it is the 2239th compound in the table to which this formula index is a part.

MELTING POINTS OF ORGANIC COMPOUNDS

The compounds below are arranged in the order of the ascending values of the melting points, an arrangement intended to serve as an aid in the identification of organic compounds. The values given may be uncertain by one or more units in the last figure and consequently are not to be used as fixed points for calibration. See special table for *Calibration of Thermometers and Thermocouples*. The numbers listed under a temperature-interval heading refer to the compounds with corresponding numerical listings in the table *Physical Constants of Organic Compounds*. Thus, under the temperature interval 186° to 190° C. is listed *No. 31* which is *acetamino-α-naphthol* m. p. 187°C.

PHYSICAL CONSTANTS OF

See also special tables on FOODS, FATS AND OILS, ALKALOIDS, GLUCOSIDES, RESINS, NOMENCLATURE, ORGANIC RADICALS, COMMON OR TRADE NAMES OF CHEMICALS, and DYESTUFF INTERMEDIATES.

Names of the compounds in the table below are arranged alphabetically. The names were selected in such a manner as to bring isomers and closely related compounds in close sequence to enable a convenient means of comparison. In general, names with prefixes such as *iso* or *tertiary* are placed with the normal compounds; thus, *isopropyl* will be found listed under *propyl*. Indented words are suffixes of the word in bold face type immediately preceding; thus, compound No. 8 is acetaldehyde ammonia. No compound is listed more than once in the table and each compound is given a number.

Synonyms are listed in two ways. In the column headed "Synonym" will be found a different name for the same compound. At the bottom of each page is an alphabetical listing for compounds which are to be found in the main body of the table but under a different name; the number following the name refers to the numerical place of this compound in the table; thus, *acetaldazine* 9 indicates that this compound is the 9th compound in the table where it will be found listed under the name *acetaldehyde azine*. Alkaloids which are listed in another table are indicated by *alkd.*; thus, *quinine, cf. alkd.*, means that this compound does not appear in the table below but will be found in a special table of alkaloids. Similarly, glucosides are indicated by *glcde.*; thus, *absinthin*, cf. *glcde.* indicates that the compound is listed in the table of glucosides.

Formulas are presented in a semi-structural form. To indicate the position of substituents on aromatic rings, position numbers are given in the same sequence as they appear in the formula; thus, in the formula "$HO{\cdot}C_6H_3(CHO){\cdot}CO_2H$ (2;5,1)", the CO_2H group is at position 1, the CHO at 5 and the OH at 2.

Beil. Ref. In the column so headed will be found the reference to the volume and page numbers of the 4th edition of Beilstein: *Handbuch der Organischen Chemie* (published by Springer, Berlin). Where the Roman numeral, which indicates the volume number, is preceded by an asterisk, reference is made to the first supplementary volumes. Thus, "*I-23", indicates that the compound will be found listed in the supplement to volume 1 and on page 23.

Formula Weights are based upon the International Atomic Weights of 1941 and are computed to the nearest hundredth.

Crystalline Form and Color. In addition to the crystalline form and color, the solvent used in purification is often given; thus, "rhb./al." indicates that rhombic

bl., black
b. p., boiling point
brn., brown
bz., benzene, C_6H_6
c., cold
carb., carbonate
chl., chloroform, $CHCl_3$
col., colorless or white
conc., concentrated
cr., crystals or crystalline
d, dextro-rotatory
d., decomposes or decomposed
delq., deliquescent
dil., dilute
diss., dissociates
dl, inactive (i. e. 50% *d* and 50% *l*)
eff., effloresces
et., ether ($C_2H_5OC_2H_5$)
Et, ethyl (C_2H_5)
expl., explodes
fl., flakes
gly., glycerol
gn., green
gr., gray
h., hot
hex., hexagonal
hyg., hygroscopic
i., insoluble

No.	Name	Synonym	Formula	Beil. Ref.	Formula Weight
1	**Abietic acid**	sylvic acid	$C_{20}H_{30}O_2$	.....	302.44
2	**Acenaphthene**	naphthylene ethylene	$C_{10}H_6(CH_2)_2$	V-586	154.20
3	**Acenaphthylene**	.....	$C_{12}H_8$	V-625	152.18

ORGANIC COMPOUNDS

crystals were obtained when the compound was crystallized from alcohol. Where no color is stated it may generally be inferred that the material is colorless.

Specific Gravity values are given at room temperatures (15 to 20°C.) unless otherwise indicated by the small figures which follow the value; thus, "$1.069^{95°}_{5°}$" indicates a specific gravity of 1.069 for the substance at 95°C. referred to water at 95°C. Specific gravity of gases with the notation "(A)" or "(D)" indicate the density of the gas referred to (A) air = 1 or (D) hydrogen = 1 respectively. See also special tables.

Melting Point is recorded in a certain case as "82 d." and in some other case as "d. 82", the distinction being made in this manner to indicate that the former is a melting point with decomposition at 82°C., while in the latter decomposition only occurs at 82°C. Where a value such as "$-2H_2O$, 82" is given it indicates loss of two moles of water per formula weight of the compound at a temperature of 82°C.

Boiling Point is given at atmospheric pressure (760 mm of mercury) unless otherwise indicated; thus, "82^{15mm}" indicates the boiling point is 82°C. when the pressure is 15 mm.

Solubility is given in parts by weight (of the formula shown at the extreme left) per 100 parts by weight of the solvent; the small exponent indicates the temperature in degrees C. In the case of gases the solubility is often expressed in some manner as "$5^{10°}$ cc." which indicates that at 10°C., 5 cc. of the gas are soluble in 100 grams of the solvent.

Dicetyl 2866 Dichloro-acetoacetanilide 42

No.	Name	Synonym	Formula	Beil. Ref.	Formula Weight
	Dichloro				
1949	azo-dicarbonamide	azochloramide	$[Cl{\cdot}N{:}C(NH_2){\cdot}N{:}]_2$		183.01
1950	azoxybenzene	(4,4′)	$(ClC_6H_4)_2N_2O$	XVI-625	267.11
1951	barbituric acid (5,5)	dichloromalonyl-urea	$Cl_2C(CONH)_2CO$	XXIV-472	196.99
1952	benzene (*o*)		$C_6H_4Cl_2$	V-201	147.01
1953	benzene (*m*)		$C_6H_4Cl_2$	V-202	147.01
1954	benzene (*p*)		$C_6H_4Cl_2$	V-203	147.01
1955	benzene sulfonic acid (2,5)		$Cl_2C_6H_3{\cdot}SO_3H$	XI-55	227.07
1956	benzene sulfonyl chloride (3,4)		$Cl_2C_6H_3{\cdot}SO_2Cl$	*XI-16	245.52
1957	benzidine (3,3′)		$(H_2N{\cdot}C_6H_3Cl)_2$	XIII-234	253.13
1958	benzidine HCl	(3,3′)	$C_{12}H_{10}N_2Cl_2{\cdot}2HCl$	XIII-234	326.06
1959	benzoic acid (2,3)		$Cl_2C_6H_3{\cdot}CO_2H$	IX-342	191.02
1960	benzoic acid (2,4)		$Cl_2C_6H_3{\cdot}CO_2H$	IX-342	191.02
1961	benzoic acid (2,5)		$Cl_2C_6H_3{\cdot}CO_2H$	IX-342	191.02
1962	benzoic acid (2,6)		$Cl_2C_6H_3{\cdot}CO_2H$	IX-343	191.02
1963	benzoic acid (3,4)		$Cl_2C_6H_3{\cdot}CO_2H$	IX-343	191.02
1964	benzoic acid (3,5)		$Cl_2C_6H_3{\cdot}CO_2H$	IX-344	191.02
1965	benzophenone (2,4′)		$(Cl{\cdot}C_6H_4)_2CO$	VII-420	251.11
1966	benzophenone (4,4′)		$(Cl{\cdot}C_6H_4)_2CO$	VII-420	251.11
1967	benzoylene urea (6,8)	Sheibley's reagent	$Cl_2C_6H_2{\cdot}NH{\cdot}CO{\cdot}NH{\cdot}CO$		231.04
1968	1-bromoethane (1,1)		$CH_3{\cdot}CCl_2Br$	I-90	
1969	1-bromoethane (2,2)		$Cl_2CH{\cdot}CH_2Br$	I-90	
1970	bromomethane		Cl_2CHBr	I-67	163.85
1971	butane (1,1)(*n*)	butylidene di-chloride	$C_2H_5CH_2CHCl_2$	I-119	127.02
972	butane (1,2)(*n*)	butylene chloride	$C_2H_5{\cdot}CHCl{\cdot}CH_2Cl$	*I-38	127.02
973	butane (1,4)(*n*)	tetramethylene diCl	$ClCH_2(CH_2)_2CH_2Cl$	I-119	127.02
974	butane (*iso*)	1,1-dichloro-2-methyl-propane	$(CH_3)_2CH{\cdot}CHCl_2$	I-126	127.02
975	butane (*iso*)	1,3-dichloro-2-methyl-propane	$(ClCH_2)_2CH{\cdot}CH_3$	**I-88	127.02
976	butane (*iso*)	1,2-dichloro-2-methyl-propane	$(CH_3)_2CCl{\cdot}CH_2Cl$	I-126	127.02
977	butyl alcohol (*tert*)		$(CH_2Cl)_2COH{\cdot}CH_3$	I-382	143.02
978	butyric acid (α,β)	crotonic acid diCl	$CH_3(CHCl)_2CO_2H$	II-279	157.00
979	butyric acid	*iso*-crotonic acid diCl	$CH_3(CHCl)_2CO_2H$	II-279	157.00
980	1,2-dibromoethane	(1,1)	$BrCH_2{\cdot}CBrCl_2$	I-93	256.78
981	1,2-dibromoethane	(1,2)	$ClBrCH{\cdot}CHBrCl$	I-93	256.78
982	1,1-dibromoethane	(2,2)	$Br_2CH{\cdot}CHCl_2$	I-93	256.78
983	dibromomethane		Cl_2CBr_2	I-68	242.76
984	diethyl carbonate	(β,β')	$(ClCH_2CH_2O)_2CO$	**III-5	187.03
985	diethyl sulfide (β,β')	mustard gas	$(Cl{\cdot}CH_2CH_2)_2S$	I-349	159.08

Thiotolene 4389
Thujin, cf. glcde.
Thymine 4413
Thymiode 5940
Thymiodol 5940
Thymodin 5940
Thymol-hexahydride 4024

No.	Name	Synonym	Formula	Beil. Ref.	Formula Weight
5942	**Thymol** sulfonic acid (*α*)	(3,6;1,4)	$(CH_3)(C_3H_7)C_6H_2$: $(OH)SO_3H \cdot H_2O$	XI-267	248.29
5943	**Thymoquinone**	.....	$O:C_6H_2(CH_3)\cdot(C_3H_7):O$	VII-662	164.20
5944	**Thymotic acid** (*o*)	(1,4;3,2)	$(CH_3)(C_3H_7)C_6H_2$: $(OH)CO_2H$	X-280	194.22
5945	**Thymyl**-acetate	acetyl thymol	$C_{10}H_{13}\cdot O_2C\cdot CH_3$	VI-537	192.25
5946	amine (1,3;4)	.....	$CH_3(NH_2)C_6H_3\cdot C_3H_7$	XII-1171	149.23
5947	**Thyroxine** (*l*)	.....	$C_{15}H_{11}O_4NI_4$	*XIV-671	776.93
5948	**Tin** chloride triphenyl	triphenyltin chloride	$(C_6H_5)_3SnCl$	*XVI-540	385.46
5949	diethyl	diethyl tin	$(C_2H_5)_2Sn$	IV-631	176.82
5950	tetraethyl	tetraethyl tin	$(C_2H_5)_4Sn$	IV-632	234.94
5951	tetramethyl	tetramethyl tin	$(CH_3)_4Sn$	IV-632	178.84
5952	tetraphenyl	tetraphenyl tin	$(C_6H_5)_4Sn$	XVI-914	427.10
5953	triethyl	triethyl tin	$[(C_2H_5)_3Sn\cdot]_2$	IV-638	411.76
5954	**Tolane**	diphenyl-acetylene	$C_6H_5\cdot C\vdots C\cdot C_6H_5$	V-656	178.22
5955	**Tolidine** (*o*)	3,3'-di Me-benzidine	$(CH_3\cdot C_6H_3\cdot NH_2)_2$	XIII-256	212.28
5956	hydrochloride	.....	$C_{14}H_{16}N_2\cdot 2HCl$	XIII-257	285.21
5957	sulfate	.....	$C_{14}H_{16}N_2\cdot H_2SO_4$	XIII-257	310.36
5958	disulfonic acid	(3,4;6)	$[(CH_3)(NH_2)C_6H_2\cdot SO_3H]_2\cdot 1\frac{1}{2}H_2O$	XIV-796	399.43
5959	**Tolidine** (*m*)	2,2'-di Me-benzidine	$(CH_3\cdot C_6H_3\cdot NH_2)_2$	XIII-255	212.28
5960	**Toluene**	methyl-benzene	$CH_3\cdot C_6H_5$	V-280	92.13
5961	azo-1-naphthyl-amine-2 (*o*)	(2,1;1',2'); yellow OB	$CH_3\cdot C_6H_4\cdot N:N\cdot C_{10}H_6\cdot NH_2$	XVI-373	261.31
5962	disulfonic acid	(2,4)	$CH_3\cdot C_6H_3(SO_3H)_2$	XI-204	252.25
5963	disulfonic Na	(2,4); (Na salt)	$C_7H_6O_6S_2Na_2\cdot 7H_2O$	XI-204	422.34
5964	sulfinic acid (*p*)	.....	$CH_3\cdot C_6H_4\cdot SO_2H$	XI-9	156.19
5965	sulfinic Na (*p*)	(sodium salt)	$C_7H_7O_2SNa\cdot 2H_2O$	XI-9	214.22
5966	sulfonic acid (*o*)	.....	$CH_3\cdot C_6H_4\cdot SO_3H\cdot 2H_2O$	XI-83	208.23
5967	sulfonic acid (*m*)	.....	$CH_3\cdot C_6H_4\cdot SO_3H\cdot aq.$	XI-94	172.19
5968	sulfonic acid (*p*)	.....	$CH_3\cdot C_6H_4\cdot SO_3H\cdot H_2O$	XI-97	190.21
5969	sulfonic Na (*p*)	(sodium salt)	$C_7H_7O_3SNa\cdot 2H_2O$	XI-97	230.22
5970	**Toluenesulfonyl**-amide (*o*)	toluenesulfonamide	$CH_3\cdot C_6H_4\cdot SO_2\cdot NH_2$	XI-86	171.21
5971	amide (*p*)	.....	$CH_3\cdot C_6H_4\cdot SO_2\cdot NH_2$	XI-104	171.21
5972	anilide (*p*)	toluene-sulfonanilide	$CH_3\cdot C_6H_4\cdot SO_2\cdot NH\cdot C_6H_5$	XII-567	247.30
5973	*n*-butylamide (*p*)	.....	$CH_3\cdot C_6H_4\cdot SO_2\cdot NH\cdot C_4H_9$	.....	227.31
5974	chloride (*o*)	toluene sulfon-chloride	$CH_3\cdot C_6H_4\cdot SO_2Cl$	XI-86	190.64
5975	chloride (*p*)	.....	$CH_3\cdot C_6H_4\cdot SO_2Cl$	XI-103	190.64
5976	di-*n*-butylamide	(*p*)	$CH_3\cdot C_6H_4\cdot SO_2\cdot N:(C_4H_9)_2$	.....	283.42
5977	dimethylamide (*p*)	.....	$CH_3\cdot C_6H_4\cdot SO_2\cdot N:(CH_3)_2$	**XI-56	199.26
5978	ethylamide (*p*)	.....	$CH_3\cdot C_6H_4\cdot SO_2\cdot NH\cdot C_2H_5$	XI-105	199.26
5979	methylamide	.....	$CH_3\cdot C_6H_4\cdot SO_2\cdot NH\cdot CH_3$	XI-105	185.24
5980	methylanilide	.....	$CH_3\cdot C_6H_4\cdot SO_2\cdot N:(CH_3)(C_6H_5)$	XII-575	261.33

Tiglic acid 2426
Tiglic aldehyde 2427
T N T 6316
Tobias' acid 4505, 4549
Tolamine 1290
Tolazine 4334
Toliminazole 4137
Tolualdehyde 5985-7
Toluamide 5988-90
Tolubenzyl acetat
